TNT	2,4,6-trinotrotoluene
USACE	United States Army Corps of Engineers
UXO	unexploded ordnance
VOC	volatile organic compounds

EXECUTIVE SUMMARY

This *J-2 Range Remedial Investigation/Feasibility Study (RI/FS)* presents the results of soil, Unexploded Ordnance (UXO) and groundwater characterization, geophysical investigations, and an evaluation of remedial alternatives for contaminated groundwater associated with the J-2 Range, located at the Massachusetts Military Reservation (MMR) on Cape Cod, Massachusetts.

The J-2 Range is located in the southeast portion of the MMR and is bounded to the north by the Former K Range and to the south by the J-1 Range. From 1935 through the late 1980s, the J-2 Range was used for training and testing purposes. Activities associated with historical range uses, primarily munitions testing and disposal, have resulted in releases of energetic compounds to the soil which are the likely source of groundwater contamination beneath the site.

The groundwater underlying and downgradient of the J-2 Range is primarily contaminated by hexahydro-1,3,5-trinitro-1,3,5-triazine (RDX) and perchlorate. For groundwater investigation and data presentation purposes, the J-2 Range has been divided into two sub-areas, J-2 Range northern plume and J-2 Range eastern plume. This division between these two areas is based on the different source areas for each plume and their distinctly different migration patterns. An Upper Cape Regional Water Co-op operates three water supply wells downgradient of the J-2 Range. Water supply well WS-2 is located approximately 0.6 mile downgradient of the J-2 Range Northern plume. Water supply well WS-1 is located approximately 0.55 mile downgradient of the J-2 Range Eastern plume. For the presentation of the source area characterization, the range was subdivided into four sub-areas, based on the Conceptual Site Models (CSM) for each portion of the range.

Northern Plume

The J-2 northern groundwater plume consists of both perchlorate and RDX. The main body of the perchlorate plume, as defined by perchlorate above the Massachusetts Maximum Contaminant Level (MMCL) (2 micrograms per liter [µg/L]), is approximately 8,100-feet long and approximately 850-feet wide at the widest point and is becoming segmented into discontinuous lobes due to the operation of the J-2 Range northern extraction, treatment and infiltration (ETI) system and natural attenuation. A groundwater treatment system began operating as a rapid response action in August 2006 for the protection of public water supply well WS-2 located downgradient of the J-2 North plume. Perchlorate concentrations in the vicinity of the source area (Disposal Area 2) and in areas immediately downgradient of extraction wells, specifically at locations MW-300, MW-293, and MW-348, have decreased below the MMCL but high concentrations remain in downgradient portions of the plume between extraction wells. Elevated perchlorate concentrations also remain in the aquifer upgradient of extraction well J2EW0001 as indicated by a measurement of 115 µg/L at the recently installed MW-585M2.

The extent of the main RDX plume has diminished, due to mass removal from the J-2 Range northern ETI system and natural attenuation, to the point where concentrations of RDX above 0.6 µg/L were detected in only two wells in 2012. These wells are approximately 1,500 feet apart and are both within the capture zone of extraction well J2NEW0001. The RDX plume, as defined by concentrations above the Health Advisory (HA) (2 µg/L), is currently limited to the vicinity of MW-289M2, located in the core of the J-2 northern plume. The historic maximum RDX detection of 16.1 µg/L was measured in the source area at MW-234M2 in 2008. This well has seen a steady decline in RDX concentrations since then, dropping below 0.6 µg/L for the first time in 2012. Thus, the J-2 northern RDX plume is currently of limited extent and is fully enveloped within the upgradient portion of the larger perchlorate plume. The Conceptual Site Model, based on known range use activities and the presence of soil contaminants, suggests disposal activities, including burning, at Disposal Area 2 as the major source of the J-2 Range northern plume.

Soil and geophysical investigations began in 1997 and continued to 2010. The result of soil investigations shows soil contamination that is consistent with contamination found in downgradient groundwater. Of the known disposal areas identified during the investigation, Disposal Area 2 is the source area most likely responsible for development of the northern plume. Explosives and perchlorate soil contamination associated with this source area was removed and thermally treated on-site in 2004.

Eastern Plume

The J-2 Range eastern plume is also comprised primarily of perchlorate and RDX. The extent of the main body of the J-2 Range eastern perchlorate plume, as defined by perchlorate above the MMCL (2 µg/L), is approximately 4,250 feet long and approximately 1,700-feet wide at its widest point. A groundwater treatment system began operating as a rapid response action in August 2008 for the protection of public water supply well WS-1 located downgradient of the J-2 East plume. The main body of the plume has become segmented due to the operation of the J-2 Eastern ETI system. Although perchlorate concentrations in the central portion of the plume between MW-368 and MW-335 remain elevated, most recently 45.0 µg/L to 75.6 µg/L (MW-368M1/M2, respectively), this portion of the plume lies within the capture zone of the J-2 eastern treatment system. To the east of the main plume are several smaller lobes of contamination, two of which have concentrations exceeding the MMCL. Concentrations in the western perchlorate lobe have decreased below 1 µg/L and are detached from the source. Low concentrations of perchlorate (below the 2 µg/L MMCL) that lie beyond the capture zone of J2EW0006 are expected to attenuate before reaching downgradient monitoring well MW-436.

The overall centerline length of the RDX plume, as defined by the 0.60 µg/L contour, is approximately 5,800 feet, extending from the source area downgradient to approximately 1,650 feet downgradient of extraction well J2EW0006 and the plume is approximately 1,150 feet at its widest point. The main body of the RDX plume is becoming segmented due to the operation of the J-2 Eastern ETI system. The core of the RDX plume is roughly coincident with the core of the perchlorate plume with recent concentrations of 5.6 µg/L and 17.6 µg/L in MW-368M1/M2, respectively.

The Conceptual Site Model, based on known range use activities and the presence of soil contaminants, suggests firing, munitions testing and disposal activities as the major source of the eastern plume.

Soil investigations began in 1997 and continued through 2009. Explosive contaminated soils were detected in the Range Road Burn Areas, FFP-3, FFP-4, FFP-5, the Twin Berms, Berm 2, Disposal Area 1, Target Control Pits, Grids in and around M19/M20 and disposal pits (Grids I12, I16, J16 and H17). These likely primary sources of groundwater contamination to the eastern plume have been removed.

Risk Screening

A soil risk screen was conducted to evaluate the risk to human health and to evaluate the potential for detected analytes in soil to leach from the soil and migrate through the subsurface to the groundwater. The risk screen identified concentrations of 2,4-DNT, HMX, RDX and perchlorate detections exceeding the screening criteria. In addition, many of these locations are associated with BIP activities and either were allowed to remain in-place under BIP protocols or are scheduled for removal under this program. Other contaminants were occasionally detected above screening levels but only at low frequencies. Based on the above findings, there is no further removal action warranted for soils at the J-2 Range. However, additional sampling will be conducted.

A groundwater risk screening was conducted for the J-2 Range groundwater. The screening identified RDX and perchlorate at concentrations exceeding the screening criteria, and were therefore recommended for further evaluation in the Feasibility Study. Several other compounds were also identified at concentrations exceeding the risk screening criteria, but these compounds were detected infrequently, are associated with naturally occurring background conditions, or are laboratory-related contaminants and therefore were not recommended for further consideration in the groundwater Feasibility Study.

Munitions

Intrusive investigations identified multiple munitions disposal areas in the northern, central and southern portions of the J-2 Range. These MEC disposal areas have been the basis of significant MEC clearance and soil removal actions. General disposal activities occurred throughout the J-2 Range and were associated with the munitions testing. The vast majority of mortars found were inert or inert bodied with live fuzes, some HE models were discovered. Based on the geophysical investigations, remaining geophysical anomalies are likely munitions debris or other metallic debris. However, there is the potential for residual MEC items, likely consisting of inert projectiles with live fuzes or isolated individual HE items, which could potentially impact the time to cleanup projected in the alternatives modeling. However, confirmational geophysical investigations will be conducted.

<u>Feasibility Study</u>

A Feasibility Study was prepared to describe the development and evaluation of remedial action alternatives for the J-2 Range northern and eastern groundwater study areas. The Feasibility Study alternatives were developed to achieve the following response action objectives: to restore the useable groundwater to its beneficial use wherever practicable, within a timeframe that is reasonable given the particular circumstances of the site; to provide a level of protection in the aquifer that takes into account that the Cape Cod aquifer, including the Sagamore Lens, is a sole source aquifer that is susceptible to contamination; and to prevent ingestion and inhalation of groundwater containing contaminants of concern (COCs) in excess of federal maximum contaminant levels, Health Advisories, drinking water equivalent levels (DWELs), applicable state standards or an unacceptable excess lifetime cancer risk or non-cancer Hazard Index. Estimated cleanup time frames and costs for each alternative are summarized in Table 10-1 (Note: since the extent of the J-2 northern RDX plume has decreased to the point that it is fully enveloped by the larger perchlorate plume, cleanup of the RDX plume is expected to occur simultaneously with the perchlorate cleanup, so separate estimates for RDX remediation time frames were not developed for the J-2 northern RDX plume.) The following alternatives were evaluated:

Alternative 1 – No Further Action

Monitoring wells and the existing treatment system would be abandoned and site close-out documentation would be completed. The source area soils have been removed. For the northern plume, perchlorate concentrations are predicted to decrease, through natural attenuation process, to below 2 µg/L by approximately 2065. Perchlorate concentrations above 2 µg/L may reach the Gibbs Road area under this alternative. For the eastern plume, perchlorate concentrations are predicted to decrease, through natural attenuation process, to below 2 µg/L by approximately 2104 and would likely migrate well beyond Gibbs Road at concentrations above 2 µg/L. RDX concentrations are predicted to decrease, through natural attenuation processes, to below 2 µg/L by approximately 2028 and to below 0.6 µg/L by 2055. Concentrations above 0.6 µg/L would likely migrate just beyond MW-436 under this alternative. The response action would be complete when the existing groundwater-monitoring-well network is abandoned. The present value cost of this alternative is $0.21 million for the northern plume and $0.24 million for the eastern plume.

Alternative 2 – Monitored Natural Attenuation and Land-Use Controls

Alternative 2 includes long-term groundwater monitoring and land-use controls, although the existing treatment system would be removed. The source area soils have been removed. For the northern plume, perchlorate concentrations are predicted to decrease, through natural attenuation processes, to below 2 µg/L by approximately 2065. Perchlorate concentrations above 2 µg/L may reach the Gibbs Road area under this alternative. For the eastern plume, perchlorate concentrations are predicted to decrease, through natural attenuation processes, to below 2 µg/L by approximately 2104 but may migrate well beyond Gibbs Road at concentrations above 2 µg/L but would remain within the base boundary. RDX concentrations are predicted to decrease, through natural attenuation processes, to below 2 µg/L by approximately 2028 and to below 0.6 µg/L by 2055. RDX concentrations above 0.6 µg/L would likely migrate just beyond MW-436 under this alternative. The Army may propose that the response action is complete, and request regulatory concurrence, when two years of monitoring in conjunction with groundwater modeling indicate that the goals have been achieved. The present value cost of this alternative is $2.8 million for the northern plume and $3.2 million for the eastern plume.

J-2 Northern Plume

Alternative 3 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land-Use Controls (Existing System)

Alternative 3 would provide for operation of the J-2 Range northern groundwater plume rapid response action (RRA) extraction treatment injection (ETI) system. The J-2 Range northern groundwater plume RRA ETI system consists of wells J2EW0001 pumping at 75 gpm, J2EW0002 pumping at 175 gpm, and J2EW0003 pumping at 125 gpm, for a combined pumping rate of 375 gpm and four infiltration trenches located to the northeast, southeast, southwest, and northwest of the northern J-2 plume. Active treatment of the plume removes perchlorate and RDX from the extracted groundwater and returns the treated water to the aquifer. The source area soils have been removed. Perchlorate concentrations are predicted to decrease below 2 µg/L by approximately 2029 and may reach the Gibbs Road area at concentrations above 2 µg/L under this alternative. The present value cost for this alternative is $5.8 million.

Alternative 4 – Focused Extraction with Three Extraction Wells, Monitored Natural Attenuation and Land-Use Controls (Existing System Optimized)

Alternative 4 involves optimization of pumping rates within the existing J-2 Range northern groundwater ETI system. The conceptual design for Alternative 4 involves optimizing the pumping rates within the existing J-2 Range northern groundwater ETI system. The conceptual design includes a flow rate at J2EW0001 of 150 gpm, a flow rate at J2EW0002 of 100 gpm, and a flow rate at J2EW0003 of 125 gpm, for a total combined pumping rate of 375 gpm. The upgradient extraction well was simulated to extract contaminant mass deep within the aquifer. The current J-2 Range northern treatment facility would need to be expanded to treat the additional flow and the effluent would be returned to the aquifer through expanding the existing infiltration trenches. The source area soils have been removed. Perchlorate concentrations are predicted to decrease below 2 μg/L by approximately 2027 and may reach the Gibbs Road area at concentrations above 2 μg/L. The present value cost for this alternative is $5.3 million.

Alternative 5 – Focused Extraction with Five Extraction Wells, Monitored Natural Attenuation and Land-Use Controls

Alternative 5 involves the optimization of pumping rates within the existing J-2 Range northern groundwater ETI system and the addition of two new extraction wells. The conceptual design for Alternative 5 includes a flow rate at J2EW0001 of 150 gpm, a flow rate at J2EW0002 of 200 gpm, a flow rate of 125 gpm at J2EW0003, and two new extraction wells (one shallow at 100 gpm and one deep at 50 gpm) would be installed for a total combined pumping rate of 625 gpm. The current J-2 Range northern treatment facility would need to be expanded to treat the additional flow and the effluent would be returned to the aquifer through expanding the existing infiltration trenches. The source area soils have been removed. Perchlorate concentrations are predicted to decrease below 2 μg/L by approximately 2024 and may reach the Gibbs Road area at concentrations above 2 μg/L. The present value cost for this alternative is $10.7 million.

J-2 Eastern Plume

Alternative 3 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land-Use Controls (Existing System)

Alternative 3 would provide for operation of the J-2 Range eastern groundwater plume rapid response action (RRA) ETI system. The J-2 Range eastern groundwater plume RRA ETI system consists of wells J2EW0004 pumping at 90 gpm, J2EWW0005 pumping at 210 gpm, and J2EW0006 pumping at 125 gpm for a combined rate of 425 gpm, and three infiltration trenches located to the northeast, southeast, and southwest of the eastern J-2 plume. Active treatment of the plume removes perchlorate and RDX from the extracted groundwater and returns the treated water to the aquifer. This alternative includes the option of modifying the system to optimize the system performance. The source area soils have been removed. Perchlorate concentrations are predicted to decrease below 2 μg/L by approximately 2027 and likely would not migrate significantly beyond the Wood Road area. RDX concentrations would decrease below 2 μg/L by approximately 2017 and to below 0.6 μg/L by approximately 2023. RDX concentrations above 0.6 μg/L would likely migrate to the west of but not beyond MW-436 under this alternative. The present value cost for this alternative is $5.5 million.

Alternative 4 – Focused Extraction with Three Extraction Wells, Monitored Natural Attenuation and Land-Use Controls (Existing System Optimized)

Alternative 4 involves the optimization of pumping rates within the existing J-2 Range eastern groundwater ETI. The conceptual design for Alternative 4 involves the optimization of the pumping rates of the existing J-2 Range eastern groundwater ETI system. The conceptual design involves a flow rate at J2EW0004 of 120 gpm, a flow rate at J2EW0005 of 250 gpm, and a flow rate at J2EW0006 of 125 gpm for a total combined pumping rate of 495 gpm. The current J-2 Range eastern treatment facilities would need to be expanded to treat the additional flow and the effluent would be returned to the aquifer through expanding the existing infiltration trenches. The source area soils have been removed. Perchlorate concentrations are predicted to decrease below 2 µg/L by approximately 2027 and likely would not migrate significantly beyond the Wood Road area. RDX concentrations are expected to decrease below the HA of 2 µg/L by approximately 2017 and below 0.6 µg/L by 2022 RDX concentrations above 0.6 µg/L would likely migrate to the west of but not beyond MW-436 under this alternative. The present value cost for this alternative is $6.0 million.

Alternative 5 – Focused Extraction with Five Extraction Wells, Monitored Natural Attenuation and Land-Use Controls

Alternative 5 involves the continued operation of the existing J-2 Range eastern groundwater ETI system. The conceptual design involves the optimization of the pumping rates of the existing J-2 Range eastern groundwater ETI system and the installation of two new extraction wells. The conceptual design involves a flow rate at J2EW0004 of 150 gpm, a flow rate at J2EW0005 of 250 gpm, a flow rate at J2EW0006 of 125 gpm, and installation of two new extraction wells (upgradient of J2EW0005) operating at a flow rate of 175 gpm and 150 gpm for a total combined pumping rate of 850 gpm. The current J-2 Range eastern treatment facility would need to be expanded to treat the additional flow and the effluent would be returned to the aquifer through expanding the existing infiltration trenches. The source area soils have been removed. Perchlorate concentrations are predicted to decrease below 2 µg/L by approximately 2022 and likely would not migrate significantly beyond the Wood Road area. RDX concentrations are expected to decrease below the HA of 2 µg/L by approximately 2016 and below 0.6 µg/L by 2021. RDX concentrations above 0.6 µg/L would likely migrate to the west of but not beyond MW-436 under this alternative. The present value cost for this alternative is $9.5 million.

1.0 INTRODUCTION

This J-2 Range Remedial Investigation/Feasibility Study provides a summary of activities conducted and data gathered for characterization of soil, unexploded ordnance (UXO) and groundwater contamination at the J-2 Range. The J-2 Range is among several training areas, ranges, and other sites evaluated by the Impact Area Groundwater Study Program (IAGWSP) for potential groundwater impacts. The J-2 Range investigation and cleanup were conducted under the authority of United States Environmental Protection Agency Safe Drinking Water Act Administrative Orders SDWA 1-97-1019, and SDWA 1-2000-0014 and in consideration of the substantive cleanup standards of the Massachusetts Contingency Plan (MCP).

1.1 Purpose of Report

The purpose of this report is to document the site characterization activities conducted for the J-2 Range, the results of J-2 Range investigations, remedial actions completed to date, the nature and extent of UXO on the range, the nature and extent of soil and groundwater contamination, and potential impacts to groundwater quality and the risks associated with the contamination. This report also includes a Feasibility Study, which evaluates remedial actions for groundwater contaminants.

1.2 Report Organization

Section 2.0 of this report provides a site description of the J-2 Range, presents the history of past military and testing activities conducted at the range and describes the physical characteristics of the site. Section 3.0 presents a summary of groundwater and source characterization activities, findings and nature and extent of groundwater contamination. Section 4.0 describes source removal activities. The conceptual site model is presented in Section 5.0. The soil and groundwater risk screening is presented in Section 6.0. Section 7.0 presents the remedial investigation findings. Section 8.0 introduces the groundwater feasibility study. Section 9.0 discusses the development of alternatives. Detailed analysis of the alternatives is presented in Section 10.0, while Section 11.0 provides the comparative analysis of alternatives.

2.0 SITE BACKGROUND

The Massachusetts Military Reservation (MMR) includes Camp Edwards, Otis Air National Guard Base, United States Coast Guard Air Station Cape Cod, Cape Cod Air Force Station, and the Veteran's Affairs Cemetery. It is located on the western side of Cape Cod, Massachusetts (Figure 2-1). The J-2 Range is located southeast of the Impact Area and northeast of the J-1 Range.

2.1 Site Description

The J-2 Range is located adjacent to (and partially within) the Impact Area and is the northernmost of four former military training, and defense contractor, test ranges that operated from the 1930s until the 1990s.

The J-2 Range is approximately 3,900 meters long and between 100- and 300-meters wide (Figure 2-2). The range is oriented southeast to northwest, with the southeastern "uprange" end near Greenway Road and the northwestern "downrange" end extending several hundred meters beyond Chadwick Road into the impact area. A dirt road runs down the entire length of the range. The terrain is undulating with natural and man-made depressions but no surface water bodies of any kind. There were five man-made berms located at various areas within the range. Two "twin" berms were located toward the southeastern end of the range. Berm 1 is located in the southwestern portion of the range. Berm 2 was located in the mid-range area and Berm 5 is located in the northwest portion of the range. A low berm runs sporadically along the edges of the range but is more prominent in the northern extension of the range. The only remaining structures located on the range are a concrete/earthen wall, an ammunition bunker surrounded by fencing, a wooden subsurface vault that housed valves/well, and the foundation of a small concrete melt/pour facility. Access to the J-2 Range is restricted by a locked gate located at Greenway Road. Several plumes of groundwater contamination have been identified that originated from source areas on the J-2 Range. The source areas include both soil contamination and UXO (or munitions and explosives of concern [MEC]) that may be in or on the soil. The J-2 Range groundwater study area is depicted on Figure 2-3. The current layout and features of the J-2 Range is depicted in Figure 2-4.

2.2 Site History

The J-2 Range was used for several purposes. From 1935 through the late 1980s, the U.S. military utilized an area that overlaps the southeast corner of the J-2 Range for small arms training. Defense contractors also used the J-2 Range from the 1950s through the late 1980s for multiple purposes that included propellant and fuze testing, munitions penetration testing, fragmentation and obscuration testing, and infrared testing of tank heat signatures. Collectively, these activities necessitated the loading of munitions with explosives, burning unused propellants, general waste burning, and munitions disposal. Aerial photographs of the J-2 Range are presented in Figures 2-5 through 2-8.

2.2.1 Musketry Range (1935 to 1940s)

The original designation of this range was Musketry Range Number 1 or J Range and was used for the instruction of non-commissioned officers in the technique of fire distribution and control of firepower. The range consisted of ten operating pits for targets. As units patrolled the range, targets would pop up - symbolizing enemy fire. It was the NCO's responsibility to build a firing line and achieve correct fire distribution. Although available documentation does not indicate the type of weaponry used on the range, it is surmised that small arms ammunition such as cal .30 ball rounds were most likely used (USACE 1999a).

2.2.2 J-2 Transition Range (1940s to 1960s)

The original J-2 Range was established in the late 1940s as a rifle transition range in the area of the current N Range. It is evident from the 1955 aerial photograph (Figure 2-5) that the transition range was in use during these timeframes, as paths to presumed pop-up targets/target control pits are easily seen. The USACE (1999a) surmised that the J-2 Transition Range was similar in nature to the J-1 Transition Range and that small arms ammunition such as cal .30 ball rounds and tracer rounds were fired. Eight firing lanes in the J-2 Range were oriented northwest/southeast with each lane having pop-up targets originating in target control pits spaced 25 to 50 yards apart, up to 500 yards from the firing points (USACE 1999a). Use of J-2 Range as a transition range lasted until the late 1960s.

2.2.3 J-2 Rifle Range (1950s to 1980s)

The J-2 Range became a 25-meter rifle range in the 1950s. The 25-meter rifle range was established south and east of the contractor areas and exists at the site of current N Range (Figure 2-5). The number of firing points at the 25-meter rifle range at the time of establishment is unknown. Between 1986 and 1989, the 25-meter rifle range had 55 firing points and 5.56mm ball and tracer ammunition was authorized for use on the range. Direction of fire is to the northwest and a backstop berm is still present on the range.

2.2.4 Contractor Test Range

The information available about the specific activities DoD contractors carried out at the J-2 Range was obtained primarily through interviews; little or no historical documentation was discovered during the search of historical records (USACE 1999a, b).

From 1953 to 1979, the majority of the J-2 Range area was utilized as a test range by the Hesse-Eastern Company. The expansion of the J-2 Range to support Contractor activities is evident in 1955 and 1966 aerial photographs (Figures 2-5 and 2-6). Records indicate that MIT and Raytheon subleased a portion of J-2 Range in the early 1980s (see below); however, both organizations reported that they either did not lease or have any record of leasing any part of J-2 Range.

The following is a list of activities that reportedly occurred at the J-2 Range. Note that the time, duration and specific location of the firing point and/or target within the J-2 Range of each type of activity is not known unless specified below. The following list is based on the J-2 Range Work Plan (Ogden 2000).

<u>Munitions Testing</u> – The following munitions testing reportedly occurred at times from the 1950s to 1980s at J-2 Range:

- T301 fuzes for the 30-mm high explosive incendiary (HEI) cartridge testing occurred between 1954 and 1957;
- Propellants and fuzes in 81mm mortars – Testing of propellants and fuzes in 81mm mortars consisted of firing inert rounds with live fuzes. The mortars were reported to be fired straight up and down to a height of 400 to 500 feet and then retrieved. The number of rounds fired is not known;

- Fuzes in 105mm and 155mm projectiles and 8-inch rounds – Inert rounds with live fuzes were fired;
- Fin assemblies of wax-filled 60mm mortars – Firing of the wax-filled 60mm mortars was performed with minimal propellant charges. The mortars contained a small amount of powdered dye for spotting purposes. Approximately 80% of the rounds fired were inert and all contained a minimal amount of propellant;
- M60 tank rounds (note: reports from MIT indicate this testing took place on J-1 Range);
- A two-day test was conducted with 40mm practice grenades to determine the effects of firing plastic-nosed rounds in extremely cold temperatures; and
- Other miscellaneous testing included testing of 2.75-inch and 3.5-inch rockets, ARAM missiles, development of M203 grenade launchers, heat, cold and drop testing of unspecified crated rounds (USACE 1999a), and reported testing by Raytheon of firing mortars from the former cement pad to try and induce lightning strikes.

The number of each of these munitions rounds that were fired is not known with the exception of the wax-filled 60mm mortars, of which between 3,000 and 4,000 were estimated to have been fired.

<u>Development of the M72 Light Anti-Armor Weapon (LAW) Rocket</u> – Testing for the development of the LAW rocket was conducted between 1971 and 1974. The firing line was located approximately 100 yards from the former J-2 Range office. Penetration tests were conducted for the 66mm HEAT round where the munitions were fired into steel-plate targets at Berm 2, 100 yards away. An estimated 1,000 rounds, most of which were HE, were fired on J-2 Range (USACE 1999a). In addition, 35mm subcaliber rounds were also fired and tested for use as a training round for the LAW. The LAW rocket launchers were reportedly assembled elsewhere. Once used, the launchers were reportedly crushed by a tank on the test range and either taken to the MMR landfill or to a local salvage yard.

<u>Melt/Pour Facility</u> – An on-site, melt/pour facility was used at the J-2 Range to melt, mix, and mold explosives (e.g., octol, RDX, and composition B) for use in various munitions including LAW rockets, mortar rounds, and 105mm rounds. Reports indicate that residue from the floor was collected and blown up on the J-2 Range, but the location is not known. Fragmentation testing was reportedly performed inside the melt/pour facility.

Buildings and structures formerly existed in the uprange (investigation Area 1) portion of the range (Figure 3-12). These buildings consisted of the former melt-pour facility (buildings A and F), a frame shed (building B), a fenced ammunition supply magazine which still exists (building O), a one story concrete block building with attached frame shed reportedly used for ordnance assembly (building C), a one-story, frame building reportedly used as a garage/vehicle maintenance (building D), a single story frame building reportedly used as the main office building (building E), a reported Conex (building G), a frame shed reportedly containing hot and cold conditioning boxes (building H), a reported loading building for artillery and rocket propellant (building I), a 26-foot high observation tower (structure J), a concrete bunker (structure K), a large concrete pad (structure L), a construction trailer (structure M), pump house (structure N), and latrine (structure P). Cleanup of debris located around these structures and removal of most of the buildings and structures occurred in 1986.

Disposal Activities

Historical information indicates that various types of disposal activities occurred at the J-2 Range.

- Disposal of Propellants – Propellants from 60mm, 105 mm, and LAW rounds were reportedly burned in two pits in the approximate locations of Brick-lined Pits 1 and 2. Propellants were also reportedly burned in the middle of the range road, approximately 200 feet from the office building and around Fixed Firing Point 3.
- Disposal of Munitions – Four potential disposal locations were identified in the Final Work Plan for J-2 Range (Ogden 2000). First, Disposal Area 1 is an area in which both 105mm and 155mm rounds and rounds marked “inert” and other munitions were observed to be buried. Second, two brick-lined pits located on the west side of the range road were identified. MEC from the pits was reportedly excavated and staged in a pile at the end of Tank Alley road within the Impact Area. Personal interview information indicated that munitions were buried and burned in two unlined pits in the same vicinity as the brick-lined pits. Finally, M72 LAW overpacks, fiberglass tubes, plywood, and 2”x4”s were disposed of in an additional location of a potential disposal area, Disposal Area 5.
- Disposal of Fireworks – In the mid-1980s, dynamite and fireworks seized by law enforcement agencies were reportedly disposed of on the J-2 Range in the suspected location of Disposal Area 2. Seized weaponry was reportedly disassembled at this location by Boston ATF personnel while the Massachusetts State Police reportedly used the same area for demolition (Ogden 2000).

Additional Miscellaneous Testing – The following additional contractor testing occurred at J-2 Range:

- 105mm Tank Barrel Testing – Over-pressure testing on the 105mm tank barrels was started on the J-2 Range before moving to J-1 Range. 105mm High Explosives Anti-Tank munitions and discarding sabot rounds of steel or tungsten were fired. The number of rounds fired while at J-2 Range is not known. In addition, “graze testing,” consisting of firing inert rounds along the ground at Berm 5, was also conducted. Reportedly 98% of the rounds used in the graze testing were recovered;
- Ejection round testing was conducted for ejection seats near the former Building K;
- Infrared testing of heat signatures was conducted on tanks and 155mm artillery guns in the early 1980s (note: reports from MIT indicate this testing took place on J-1 Range); and
- Obscuration tests of smoke and dust were conducted using white phosphorous grenades (12 grenades and 6 smoke pots in total) and subsurface detonation of 105mm shells (10 shells total) in the summer of 1980.

2.2.5 Late 1980s to the Present

After DoD contractors left the range in the late 1970s, there were no specific activities documented to have occurred at the J-2 Range. Available aerial photography indicates significant revegetation has occurred (Figures 2-6, 2-7, and 2-8).

Previous Investigations have identified several features on the J-2 Range; the locations of which are depicted on Figure 2-4. Most investigations activities, as further described in Section 3.0, focused on these features. A description of each feature follows:

- Fixed Firing Point 1 (FFP1) – This structure was a fixed firing point, most likely used to mount 105mm and 155mm artillery guns. The firing point is comprised of a concrete pad within a U-shaped earthen berm.
- Fixed Firing Point 2 (FFP2) – This structure is a fixed firing point, likely used to mount 105mm and 155mm artillery guns.
- Fixed Firing Point 3 (FFP3) – This structure was used as a fixed firing point from which mortars, 105mm rounds, and LAW rockets were fired. It was also reported that excess propellant was burned near this structure.
- Fixed Firing Points 4 and 5 (FFP4 and FFP5) – These structures were fixed firing points, likely used to mount artillery guns, and possibly 57mm recoilless rifles.
- Range Road Burn Area (RRBA) – Propellants were reportedly burned in the range road at the southern portion of the range, south of Fixed Firing Point 4.
- Twin Berms (Former FFP6) – A metal platform in this area was used as a firing point for artillery guns that fired projectiles through a gap in two berms located directly in front of this position and toward the impact area.
- Mortar Position – A witness identified this area northeast of the range road as a former location of a mortar position.
- Berm 1 – Berm 1 is located in the southwestern portion of J-2 Range. This unstructured soil pile was identified as the endpoint of a cleared pathway visible on the 1966 aerial photograph originating at Fixed Firing Point 1. It may have been used as a backstop for firing points located on the southwest side of the range road (FFP1 and FFP2). No specific information from the 1960s exists about what was fired at Berm 1, but the Archive Search Report (ASR) indicates that the government contractor (Hesse Eastern) fired inert 81mm rounds with live fuzes during that time. In addition, a contractor (Lincoln) used J-2 Range for “thousands” of test firings of a wide range of munitions, including “inert mortars,” seventy-five 105mm tank rounds, LAW rockets, 81mm and 60mm mortars, 155mm projectiles, and 8-inch artillery rounds. No MEC has been found at Berm 1 during any intrusive investigation.
- Berm 2 – Berm 2 is located on the boundary between Grids O24 and O25. The 300-meter berm was used as a backstop for firing points on the northeastern side of the range road (FFP3, FFP4, FFP5).

  The ASR (page 3-19) indicates that Berm 2 was used as a backstop for LAW rocket firing practice. As shown on Figure 7 of Appendix G, munitions that have been found on or in the vicinity of Berm 2 include 66mm LAW Rockets (HE), 30mm projectiles (HE), 81mm mortars (inert), and 60mm mortars (inert).

- Berm 3 – The 100-meter berm was used as a backstop for firing points on the northeastern side of the range road (FFP3, FFP4, FFP5).
- Berm 5 – The 500-meter berm, located on the southwest side of the range road was used as a backstop for firing points at the south end of the range.
- Disposal Area 1 – This area was reportedly used for disposal of munitions.
- Disposal Area 2 – This area was reportedly used for demolition of small arms, ammunition, dynamite and fireworks. Munitions were also disposed of in this area.
- Brick-Lined Pits 1 and 2 – These pits were reportedly used for munitions disposal.
- Sherman Tank – A Sherman tank was staged on the northeast side of the range road. A witness reported that the tank was reportedly used for scrap parts and as a firing platform for 60mm and 81mm mortars.
- Latrine/Soil Pile – A latrine and adjacent soil pile were located in the southern portion of the site. Three, 55-gallon drums were buried in the soil pile. Two of the drums contained inert mortar rounds and the third drum was empty.
- Target Control Pits – A total of 61 target control pits associated with the former transition range established in the 1940s were identified. The pits were approximately 4 to 6 feet deep and could have been used for munitions disposal by defense contractors.

2.3 Environmental Setting

2.3.1 Geographic Setting

MMR includes Camp Edwards, Otis Air National Guard Base, United States Coast Guard Air Station Cape Cod, Cape Cod Air Force Station, and the Veterans Affairs Cemetery. It is located on the western side of Cape Cod, Massachusetts. The northern non-cantonment area is a wooded area on the Upper Cape that is largely undeveloped, but fringed with highways, homes, and other development (Cape Cod Commission 1998). The predominant land use surrounding MMR is residential or commercial development. MMR is situated adjacent to the towns of Bourne, Sandwich, Falmouth, and Mashpee. The J-2 Study Area is located in the southeastern portion of Camp Edwards between Greenway Road and the Impact Area.

A restricted area surrounded by fencing and guarded gates, the land is controlled by the U.S. Army under a lease with the Commonwealth of Massachusetts until at least 2051. Chapter 47 of the Acts of 2002 established the Upper Cape Water Supply to protect the water supply and wildlife habitat. Therefore, the potential for human exposure to on-site soil contaminants is limited to occasional trespassers, site workers, and military personnel. It is anticipated that the land use at the J-2 Range will not significantly change over time. An Upper Cape Regional Water Co-op operates three water supply wells. Water supply well WS-2 is located approximately 0.6 mile downgradient of the J-2 Range North plume. Water supply well WS-1 is located approximately 0.55 mile downgradient of the J-2 Range East plume.

2.3.2 Cultural Setting

Land use near MMR is primarily residential and recreational, and secondarily agricultural and industrial. Portions of MMR are opened for deer and turkey hunting by permit from the Massachusetts Division of Fisheries and Wildlife. The major agricultural land use near MMR is the cultivation of cranberries. Commercial and industrial development in the area includes service industries, landscaping, sand and gravel pit operations, and municipal landfills (USACE 2002).

MMR contains a cantonment area that includes a housing area for approximately 2,000 year-round residents. This area includes a chapel, a golf course, a base exchange, a medical dispensary, and two schools. Areas of MMR are used as airfields and other military support facilities. The MMR resident population increases by as much as several thousand people during the summer training activities.

The northern area in which the J-2 Range is located is used for military training. As such, it is a restricted area surrounded by fencing and guarded gates. The land is controlled by the U.S. Army under a lease from the Commonwealth of Massachusetts running until at least 2051. Chapter 47 of the Acts of 2002 established the Upper Cape Water Supply Reserve to protect the water supply and wildlife habitat. Therefore, the potential for human exposure to on-site soil contaminants is limited to occasional trespassers, site workers, and military personnel. It is anticipated that the land use at the J-2 Range will not significantly change over time. Upper Cape Regional Water Supply Co-operative water supply well WS-2 is located approximately 0.6 mile downgradient of the J-2 Range North plume. Water supply well WS-1 is located approximately 0.55 mile downgradient of the J-2 Range East plume.

An archaeological survey covering 72 percent of Camp Edwards was conducted in 1987 to assess its archaeological sensitivity. One historic site and 26 prehistoric sites were identified within Camp Edwards. Findings from these surveys indicate that humans inhabited the Camp Edwards area up to 10,000 years ago.

2.3.3 Ecological Setting

The northern two-thirds of MMR are characterized as undeveloped open area, while the southern one-third is characterized as developed land. The dominant vegetation types vary accordingly. The northern portion of MMR consists of forested uplands dominated by stands of pitch pine and mixed oak species (*Quercus* spp.) with a diverse shrubby understory. Remnant vegetation in the southern portion of MMR consists of open grassland fields interspersed with scattered trees and shrubs. The present composition of these forests is a reflection of eighteenth-century logging practices, replanting strategies, and fire suppression activities. The other dominant cover type in this area consists of pitch pine and scrub oak barrens that are maintained by periodic fires (USACE 2002).

There are 39 state-listed species observed on MMR. About half of these are lepidoptera (i.e., moths), such as Gerhard’s underwing moth (*Catocala herodias gerhardi*), the barrens daggermoth (*Acronicta albarufa*), and Melsheimer’s sack bearer (*Cicinnus melsheimeri*). State-listed plant species documented on MMR include broad tinker’s weed (*Triosteum perfoliatum*), ovate spikerush (*Eleocaris obtusa* var. *ovata*), Torrey’s beak-sedge (*Rhynchospora torreyana*), and adder’s tongue fern (*Ophioglossum pusillum*). Rare bird species on MMR include the upland sandpiper (*Bartramia longicauda*), the grasshopper sparrow (*Ammodramus savannarum*), the vesper sparrow (*Pooecetes gramineus*), and the northern harrier (*Circus cyaneus*). These species are primarily associated with the grassland fields in the southern cantonment area. No threatened or endangered amphibians, reptiles, fish, or mammals are known to inhabit MMR; however, MMR does support a number of animals that are listed by the state as species of special concern. These include the eastern box turtle (*Terrapene carolina*), the Cooper's hawk (*Accipiter cooperii*), and the sharp-shinned hawk (*Accipiter striatus*) (USACE 2002).

2.3.4 Climate

The climate for Barnstable County, where MMR is located, is defined as humid continental. The neighboring Atlantic Ocean has a moderating influence on the temperature extremes of winter and summer. Winds of 30 miles per hour may be expected on an average of at least one day per month. Gale force winds can be common and more severe in winter. Average daily temperatures range from 29.6 ^{o}F in February to 70.4 ^{o}F in July.

Mean annual rainfall and snow melt water ranges from 45 to 48 inches. The average net recharge to groundwater of this annual rainfall is 27 inches per year. Occasional tropical storms that affect Barnstable County may produce 24-hour rainfall events of five to six inches (NGB 1990). Average snowfall is 24 inches (MAARNG 2001).

2.3.5 Geology

The J-2 Range is situated within the Mashpee Pitted Plain, a thick wedge-shaped deposit of unconsolidated Late Pleistocene outwash sands and gravels. The Mashpee Pitted Plain is bounded to the west and north by Buzzards Bay and Sandwich moraines, respectively. The Mashpee Pitted Plain is an outwash plain formed by streams that drained the Buzzards Bay and Cape Cod Bay lobes of retreating glaciers. Depositional environments of the Mashpee Pitted Plain range from glaciofluvial for the coarser deposits to glaciolacustrine for the finer deposits. In the Mashpee Pitted Plain, the glaciolacustrine deposits are discontinuous and commonly overlie basal till or bedrock. Coarse textured basal till, consisting of poorly sorted sands and gravels, occurs sporadically across the top of the bedrock surface. Coarser grained sands and gravels, deposited in glaciofluvial environments, usually overlie the glaciolacustrine deposits and are more continuous across the plain. Overlying these glaciofluvial deposits is a thin veneer of eolian silt.

Soils encountered during installation of the numerous borings and monitoring wells within the J-2 Range are consistent with the descriptions of the Mashpee Pitted Plain stratigraphy, and depths to bedrock surface. The principal soil stratigraphic lenses identified at the J-2 Range are indicated in range cross-sections (Figures 2-11 through 2-15). The top 260 feet consists predominantly of poorly graded medium to coarse sands with intervals of fine gravelly sediments and is classified using the Unified Soil Classification System as SP. Between 260 and 330 feet, soils are principally classified as finer sands and silts. These deposits are representative of a sandy basal till. Crystalline bedrock was encountered at a depth of approximately 320 to 380 feet below grade. Additional detailed information on the geology of the J-2 Range can be found in the *Draft J-2 Range Groundwater Remedial Investigation and Feasibility Study* (ECC 2007).

2.3.6 Hydrogeology

The J-2 Range groundwater study area is located within the Sagamore Lens of the Western Cape Cod aquifer. Numerous groundwater investigations have been conducted for the SE Range plumes. These investigations have addressed many aspects of the hydrogeologic conditions pertinent to the J-2 Range. A general description of the hydrogeologic setting for the

Southeast Ranges is provided in the Draft J-2 Range Groundwater Remedial Investigation and Feasibility Study (ECC 2007). This section summarizes the water table and top of mound characteristics, hydraulic gradients and groundwater flow velocities.

The aquifer system beneath MMR is unconfined (i.e., it is in equilibrium with atmospheric pressure and is recharged by infiltration from precipitation). The sole source of natural fresh water recharge to this groundwater system is rainfall and snow melt water that averages approximately 48 inches per year. Except on extreme slopes, surface water runoff at Camp Edwards is virtually nonexistent due to the highly permeable nature of the sand and gravel underlying the area.

2.3.6.1 Water Level Elevations

Water level elevation data in the Southeast Ranges collected in 2000, 2003, and 2004, along with water level contours and top of mound positions are presented in the Draft J-2 Range Groundwater Remedial Investigation and Feasibility Study (ECC 2007).

Water level elevation data in the J-2 Range groundwater study area have been collected since 1997. Data sets acquired after 1999 have more spatial coverage than earlier data sets. The data collected from June to December 2000 were composited and used to evaluate long-term average water levels. The synoptic surveys from August 2003 and May 2004 are the most comprehensive for the J-2 groundwater study area and have provided insight on the top of the mound (TOM) position within the J-2 Range study area. Measurements taken during the July to December 2005 monitoring well sampling events provided a better correlation with the J-2 plumes' azimuth and movement.

A review of historical groundwater elevations show that water levels in upgradient portions of the J-2 Range generally vary from 67 to 69 feet msl. Water levels from 2006 in the J-2 Range were approximately 71 feet msl. Groundwater elevations in the downgradient portions of the J-2 Range groundwater study area are typically 6 to 8 feet lower than for upgradient areas. Water table maps constructed from data collected in 2000, 2002, 2003 and 2004 show the J-2 Range is just north of the TOM. From the TOM, groundwater in the study area has a radial flow pattern. Groundwater elevation contours indicate that the groundwater flow direction in the western portion of the J-2 Range (J-2 North plume) is principally north-northeast. In the eastern portion of the J-2 Range (J-2 East plume), the groundwater flow direction is northeasterly and easterly close to the TOM and generally north-northeasterly and northeasterly downgradient of the TOM.

The overall configurations of the northern and eastern groundwater plumes at the J-2 Range (Figure 2-9) are generally consistent with the predominantly northern direction of groundwater flow discussed above. The discontinuous nature of the two plumes reflects the ongoing operation of the groundwater treatment systems. The relationship of these plumes to the stratigraphic layers discussed in Section 2.3.5 is depicted in Figures 2-11 to 2-15. Detailed discussion of the nature and extent of the northern and eastern plumes is presented in Section 3.2.

2.3.6.2 Hydraulic Gradients

Synoptic groundwater elevation data sets from 2003 and 2004 were used to calculate horizontal hydraulic gradients for a series of triangular areas in the J-2 Range groundwater study area. The magnitude and direction of flow for these triangular areas are presented in Figure 3-11 and in Table 3-1 of the Draft J-2 Range Groundwater Remedial Investigation and Feasibility Study

(ECC 2007). The geometric mean for hydraulic gradients calculated from August 2003 and May 2004 data show magnitudes of 0.0004 and 0.0005, respectively. The horizontal gradient increases with distance from the TOM. Based on the August 2003 data, the gradient increases to 0.0014 near the northern terminus of the J-2 North plume. Results indicate that the dominant direction is to the northeast, with the most variability in wells located close to the TOM (i.e., MW-127, MW-122, and MW-158). In general, horizontal groundwater gradients calculated for the triangular areas are small, reflecting the relatively flat groundwater table proximate to the TOM.

Variability in both the magnitude and direction of observed hydraulic gradients reflects possible variation in actual groundwater flow direction. Gradients near the TOM are very flat and small errors in field observations can have a large impact on calculated gradients. Thus, the large variability of flow direction near the TOM presented in the triangular elements in Figure 3-11 may not be representative.

Vertical hydraulic gradients were computed for 17 nested well pairs in the J-2 groundwater study area. The chosen well pairs were within the J-2 North and J-2 East plumes and included upgradient, downgradient, and crossgradient locations (ECC 2007; Table 3-2). Vertical gradients calculated from data ranging from March 2004 to April 2006 and ranged from 0.0090 ft/ft to 0.0050 ft/ft. The resulting values indicate an essentially flat gradient as vertical gradient values less than +/- 0.01 are outside the limits of measurement precision.

2.3.6.3 Hydraulic Conductivity and Porosity

The following discussion of hydraulic conductivity for various lithologic units in the J-2 groundwater study area is based on the hydraulic conductivity (K) values that were successfully calculated from grain-size data.

As described in Section 2.3.5, the subsurface geology consists of a matrix of glaciofluvial stratified sand and gravel with a few laterally and vertically discontinuous glaciolacustrine lenses overlying glacial till. The hydraulic conductivity of sands (SP, SW) calculated from grain-size data range from 19 ft/day to 314 ft/day. The poorly graded medium and coarse sands comprise the largest volumetric percentage of the aquifer. The hydraulic conductivity of gravely sands is slightly higher, ranging from 63 ft/day to 491 ft/day. Anisotropy in sands is assumed to range from 3:1 to 10:1 depending on grain size (Masterson et al. 1997). The glaciolacustrine lenses and glacial tills within the study area were too fine grained to calculate K values.

In general, the fine-grained units have hydraulic conductivities less than 10 ft/day with anisotropies up to 100:1 (Masterson et al 1997). Hydraulic conductivity values were estimated from grain-size samples in selected borings using the Hazen and Beyer methods (Vukovic and Soro 1992) (Table 2-2). For nine of the samples, hydraulic conductivity could not be calculated, because the sieve data lacked certain values required for inputs, or because the data did not meet all of the criteria for use with the equations. This generally occurs when the sample is either too fine or too coarse to provide all of the sieve-size outputs.

Site-specific porosity data have not been collected from the study area; however, other studies on upper Cape Cod indicate that the effective porosity (ne) of the coarse sand and gravel likely ranges from 0.35 to 0.42 (Masterson et al. 1997). For groundwater modeling and plume shell-based estimates of mass, an effective porosity of 0.30 is assumed for the study area.

2.3.6.4 Groundwater Flow Velocities

Groundwater flow velocities (v) are dependent on hydraulic conductivity, gradients, and effective porosity and are a key factor for estimating travel times for groundwater plumes.

$$v = K\,(i/ne)$$

Where

K = hydraulic conductivity (ft/day)

i = horizontal gradient (ft/ft)

ne = effective porosity

For this assessment, velocities were calculated for representative hydraulic conductivity values of 75 and 150 ft/day (based on grain size). For the evaluation of velocities, horizontal gradients of 0.0004 ft/ft for the upgradient portion of the study area and 0.0014 ft/ft for the downgradient portion of the plumes were considered. Using an effective porosity of 0.3, the average linear velocities are 0.1 and 0.2 ft/day for the lowest gradient (0.0004 ft/ft). For the steepest gradient (0.0014 ft/ft), the average linear velocities increase to 0.35 and 0.70 for conductivity values of 75 and 150 ft/day, respectively.

3.0 SUMMARY OF INVESTIGATIONS

3.1 Groundwater Characterization Activities

Intensive investigation activities at the J-2 Range commenced in August 2000. Investigation activities included monitoring well installation, sample collection and analysis, synoptic water level surveys and continuous groundwater model development. A total of 203 well screens were installed in 80 locations and over 1,200 samples have been analyzed. Drilling at monitoring well locations was conducted with borewater samples collected at 10-foot intervals and analyzed for explosives by EPA method SW846/8330 and perchlorate by EPA methods E314.0 or SW846/6850. Boring logs are contained in Appendix A and all of the chemical data results are presented in Appendices C and D. Water quality parameters measured during groundwater sampling are presented in Appendix E.

All monitoring well locations were surveyed with horizontal positioning referenced to the North American Datum 1983, Universal Transverse Mercator (UTM) Zone 19 North in meters and vertical datum referenced with an accuracy of 0.005 feet of vertical/horizontal control to the North American Datum of 1927 in feet. Well locations were obtained by static Global Positioning System (GPS) occupations. Elevations were calculated using post-processing software and are referenced to the top of the PVC pipe at the designated mark (Tables 3-1 and 3-2).

Only groundwater data obtained since the data cutoff of the 2007 RI/FS are included in this document, as these data best represent current plume conditions and trends and are more relevant for the purpose of determining the success of the interim remedy and evaluating the need for any operational or infrastructure changes in the final remedy. Detailed discussion of the initial plume delineation efforts can be found in the 2007 Draft J-2 Range groundwater RI/FS, which is referenced in this document.

The most recent groundwater characterization activities included the installation of five drivepoints (DP-501, DP-502, DP-509, DP-510 and DP-511) in the J-2 Range Extension area to assess potential groundwater impacts from the Extension Area Detonation Pit and other areas of soil contamination (Figure 3-1). Drivepoint samples at each location were advanced 30 feet into the water table, with borewater samples collected at 10-foot intervals and analyzed for explosives by EPA method SW846/8330 and perchlorate by EPA method SW846/6850. Additionally, samples collected at location DP-509, directly downgradient of the Detonation Pit were also analyzed for n-nitrosodimethylamine (NDMA) by EPA method E1625. Forward particle tracks generated from DP-502, DP-509 and the Detonation Pit were used to site downgradient monitoring wells along Wood Road. The forward particle tracks from DP-502 intercepted the existing MW-302 well cluster on Wood Road; therefore, no additional monitoring wells were installed at that location. Based on the forward particle tracks from DP-509 and the Detonation Pit, MW-519 was installed. All profile samples collected from this location were analyzed for explosives by EPA method SW846/8330 and perchlorate by EPA method E314.0. Additionally, the last borewater samples collected were also analyzed for NDMA by EPA method E1625. One well screen (MW-519M1) was installed in this boring from 198 to 208 feet bgs (approximately -24 to 34 feet msl) to bridge a sole detection of perchlorate.

Five locations were drilled (BH-585, BH-586, BH-587, BH-588 and BH-589) and a total of 11 monitoring wells were installed at the J-2 northern plume from September 2012 through December 2012. These 11 MW locations are: MW-585M1, M2, M3; MW-586M1, M2; MW-587M1, M2; MW-588M1, M2; and MW-589M1, M2.

3.2 Nature and Extent of Groundwater Contamination

This section presents the analysis and interpretation of groundwater monitoring results as of 2012. Two large-scale plumes of comingled RDX and perchlorate contaminated groundwater have been found to be migrating from sources at the J-2 Range. The longitudinally elongated J-2 Range northern plume is thought to be derived from a single primary source (Disposal Area 2) located near Barlow Road and is migrating in a northerly direction. The J-2 eastern plume is more fan-shaped and consists of an elongated main lobe, which migrates in a northeasterly direction and several smaller lobes that migrate in more easterly or northerly directions, as governed by the locations of its several originating sources along the curving water table beneath the midrange area.

Historical depictions of the plumes are presented in prior year interim annual environmental monitoring reports for the two plumes. The interim annual monitoring reports provide analyses of plume dynamics and hydraulics including assessment of model-predictions against observed behavior; monitoring program effectiveness operational aspects of the rapid response action (RRA) extraction, treatment, and infiltration (ETI) system; and the in-plant effectiveness of treating extracted groundwater. ETI systems became operational at the J-2 Range northern plume in September 2006, and at the J-2 eastern plume in September 2008. The primary site-related contaminants in the northern and eastern groundwater study areas are perchlorate and RDX. Perchlorate and RDX concentrations in groundwater are presented in Tables 3-3 and 3-4. All of the chemical data results are presented in Appendices C and D and the distribution of the primary site-related contaminants are shown on maps and cross sections.

Brief descriptions of the J-2 Range northern and eastern plumes are provided below. Updated plume depictions are shown on Figures 3-1 through 3-6.

Samples were collected in accordance with the following work plans and project notes.

- *Final J-2 Range Workplan for the Camp Edwards Impact Area Groundwater Quality Study* (Ogden 2000)
- *Final J-2 Range Additional Delineation Workplan for the Camp Edwards Impact Area Groundwater Quality Study* (AMEC 2001)
- *Final J-2 Range Additional Delineation Workplan #2 for the Camp Edwards Impact Area Groundwater Quality Study* (AMEC 2002b)
- *Draft J-2 Range Supplemental Groundwater Workplan* (AMEC 2003)

3.2.1 J-2 Range Northern Plume

Perchlorate

By far the dominant constituent of the J-2 Range northern plume is perchlorate. The extent of the J-2 Range northern perchlorate plume, as defined by detections above 2 µg/L is approximately 8,100 feet long and 850 feet wide. This represents a significant narrowing of the plume since active treatment began in 2006, when the plume was observed to be approximately 1,300 feet wide at its widest point. The plume also does not extend as far upgradient as earlier depictions and is becoming segmented into discontinuous lobes, due to the operation of the J-2 Range northern treatment system and natural attenuation (Figure 3-1).

Residual perchlorate concentrations in shallow wells MW-234M1 and MW-130S, near the downgradient edge of Disposal Area 2, have been below 2 µg/L since 2008 and 2006, respectively. Additionally, perchlorate has been measured at MW-263M2 nine times from May 2003 through February 2006 where concentrations increased from 3.71 µg/L in May 2003 to a maximum of 15 µg/L in December 2003 before declining continually to 1.6 µg/L in February 2006. The deeper perchlorate detections at MW-289M1, just downgradient from the source, have continued to decrease, with the recent concentration of 0.09 µg/L (June 2012). The deeper perchlorate contamination previously detected in this well (9.2 µg/L in 2004) has not been detected in downgradient monitoring well (MW-293M1). These results indicate that previous perchlorate concentrations at MW-289M1 may not be migrating significantly downgradient.

There is evidence of segmentation of the plume downgradient of extraction well J2EW0001, as evidenced by decreasing concentrations in monitoring wells located along Wood Road. Perchlorate concentrations in all of the monitoring wells located along Wood Road, including MW-300M1 (down to 0.01J µg/L), MW-300M2 (down to 0.52 µg/L), MW-305M1 (down to 0.2 µg/L) and at MW-293M2 (down to 0.48 µg/L) within the J-2 Range northern plume, have decreasing trends and there have been no detections above 2 µg/L in any of these wells since 2008. Perchlorate concentrations are also lower at MW-322M1 with the two recent sample measurement at 0.08 µg/L in July 2012.

Perchlorate concentrations rose dramatically starting in September 2010 in well J2EW1-MW1-C, peaking at 198 µg/L in April 2011 (then dropping to 0.76 µg/L by July 2012) indicating that a significant amount of perchlorate mass remains in the plume upgradient of J2EW0001 and that the bottom of the plume is slightly deeper (approximately 10 feet) than previously depicted. The J2EW0001 predicted vertical capture zone indicates that contamination at J2EW1-MW1-C should be effectively captured; however, the overlap is marginal and optimization of this capture zone by increasing the extraction rate has resulted in more reliable capture of the upgradient perchlorate plume. Evidence of capture is also indicated by the elevated influent concentrations at this extraction well (up to 20.7 µg/L in February 2010).

In 2012, drive points BH-585 through BH-589 further verified the existence of significant perchlorate mass in the vicinity of J2EW0001, including areas that are outside the J2EW0001 capture zone but within the J2EW0002 capture zone. These results compelled a recent pumping rate optimization that doubled the pumping rate at J2EW0001 and reduced the pumping rate at J2EW0002.

Immediately downgradient of J2EW0002, perchlorate concentrations at MW-348M2 have been trace to nondetect since 2007 (down from a high of 51.6 µg/L in 2005). Perchlorate has never been detected in J2EW2-MW-1A. Further downgradient perchlorate concentrations at J2EW2-MW-3B remain strong at 21.2 µg/L (June 2012) and 12.3 µg/L (July 2012) in well MW313M2 (February 2010), indicating that there is still mass migrating downgradient toward J2EW0003.

Perchlorate and RDX had been monitored at J2EW2-MW-2A, J2EW2-MW-2B, and J2EW2-MW-2C annually since 2007 and only J2EW2-MW-2B has shown any perchlorate contamination of note, being measured at 13.6 ppb in 2007. No other perchlorate measurements were greater than 0.308 ppb in any of the other monitoring wells in the cluster since monitoring began and many measurements have been non-detect. RDX concentrations measured at these three monitoring wells have been non-detect since monitoring began. Furthermore, the J2EW2-MW-2 well cluster is predicted to have been captured by the J2EW0002 extraction well under historic extraction rates (J2EW0001 = 75 gpm, J2EW0002 = 175 gpm, and J2EW0003 = 125 gpm) and under recently optimized extraction rates (J2EW0001 = 150 gpm, J2EW0002 = 100 gpm, and J2EW0003 = 125 gpm).

Perchlorate continues to remain below detectable concentrations or at very low concentrations (less than 0.04 µg/L) cross-gradient to the east of the downgradient portion of the plume (MW-318). However, to the west, concentrations of 3.1 µg/L were measured at MW-296M1 in July and October 2012 representing a spike in concentration. Downgradient of J2EW0003, perchlorate concentrations are trending lower at J2EW3-MW2-B to 0.027J (June 2012), down from a high of 4.9 µg/L in 2007. Further downgradient results (MW-327, MW-330, MW-337, MW-340, MW-345, and MW-63) indicate that the portion of the plume that was beyond the capture zone of the treatment system has not migrated significantly downgradient at concentrations above 2 µg/L.

In the drivepoints installed in the J-2 Range Extension area, perchlorate was detected in one profile sample (DP-509, 47.14 feet msl) at a concentration of 1.9 µg/L. Profile samples were collected from drive point location DP-519 in November 2008 at depths from 101 feet below ground surface (bgs) to 178.6 feet bgs. Sonic rig drilling was initiated in January 2009 and additional profile samples were collected from 170 feet bgs to 315 feet bgs. MW-519M1 was installed from 198 feet bgs to 208 feet bgs late January 2009. Profile sample results are presented in Appendix C. Perchlorate was only detected in one profile sample (-28.54 feet msl) at a concentration of 0.37J µg/L. Subsequent rounds of sampling at MW-519M1 have shown low level detects of perchlorate, with the most recent groundwater sample, collected on 18 September 2009, containing 0.21 µg/L of perchlorate. These results indicate there is not a perchlorate plume associated with the J-2 Range Extension Area.

RDX

The extent of the main RDX plume has diminished to the point where concentrations of RDX above 0.6 µg/L were detected in only two well samples collected in 2012. RDX was not detected above 0.6 µg/L in source area well MW234M1 for the first time. The RDX plume was approximately 2,400 feet long and 900 feet wide prior to the RRA system startup in 2006. Concentrations of 2.6 µg/L and 1.9 µg/L were detected in MW-289M2 and J2EW1-MW-1C, respectively, in 2012. These wells are approximately 1,500 feet apart (Figure 3-8). RDX was also detected in three profile samples at BH-585 (now MW-585), immediately upgradient of J2EW0001, at concentrations up to 1.8 µg/L. The plume, as defined by RDX concentrations above the EPA lifetime health advisory in drinking water (HA) of 2 µg/L, is likely less than 1,500 feet long and 200 feet wide (Figure 2-10). The plume is approximately 35 feet deeper at J2EW1-MW1-C than previously conceptualized (Figure 2-11). The J2EW0001 predicted vertical capture zone indicates that contamination at J2EW1-MW1-C should be effectively captured; however, the overlap is marginal and optimization of this capture zone by adjusting the extraction rate may result in a more reliable capture of the upgradient RDX plume.

The isolated, deeper RDX detections at well MW-289M1 have been below 0.6 µg/L with 0.27 µg/L detected in 2012, down from a high of 2.1 µg/L in 2004. Downgradient of this deep monitoring well sample results remain nondetect.

RDX was detected during drilling in the J-2 Range Extension. Low levels of RDX were detected in the two deep profile samples collected at DP-502 (0.54 µg/L and 0.62 µg/L, respectively). Profile samples were collected from drive point location DP-519 in November 2008 at depths from 101 feet below ground surface (bgs) to 178.6 feet bgs. Sonic rig drilling was initiated in January 2009 and additional profile samples were collected from 170 feet bgs to 315 feet bgs. MW-519M1 was installed from 198 feet bgs to 208 feet bgs. There were no detections of RDX during the downgradient drilling at DP-519/MW-519 or during subsequent groundwater sampling at MW-519M1. The drilling and monitoring well sampling results from the J-2 Range Extension indicate there is not an RDX groundwater plume associated with the J-2 Range Extension.

3.2.2 J-2 Range Eastern Plume

Perchlorate

There are multiple sources of the J-2 Range eastern plume that have resulted in a heterogeneous plume. The extent of the J-2 Range eastern perchlorate plume (above 2 µg/L) is approximately 4,200 feet long, and 1,700 feet wide at its widest point. There are also three smaller lateral plumes (Figure 3-1). The conceptualization of the J-2 Range eastern plume has changed significantly since the 2008 startup of the J-2 Eastern ETI system. Based on hydraulic monitoring conducted during system startup the plume core is thought to be vertically bifurcated about low conductivity deposits in the area between extraction wells J2EW0004 and J2EW0005. The plume has also started to become segmented in the vicinities of the three extraction wells.

The conceptualized increase in plume length is due to an increased range of fluctuation in perchlorate concentrations at MW-393M1. Perchlorate increased from 1.8 µg/L (February 2006) to a maximum of 4.9 µg/L (October 2008) (Figure 3-9, Table 3-4). However, since 2008 samples from MW-393M1 have been trace to nondetect for perchlorate, most likely due to flushing of clean water into the well screen from above the plume due to operation of J2EW0006.

Perchlorate concentrations beneath the source area of the main lobe have continued to decrease. The current perchlorate concentration beneath the source area is 0.8 µg/L (MW-307M3, August 2012); down from a high of 25.0 µg/L (April 2007). Downgradient from the source area, concentrations in MW-321M1 have fallen from a high of 2.8 µg/L in 2005 to 0.5 µg/L in August 2012 and groundwater samples collected from J2MW-05M2, located adjacent to extraction well J2EW0004, have been trace detections to ND since September 2009.

The middle of the main lobe has narrowed slightly, based on a generally decreasing trend at MW-339M1 (1.6 µg/L, August 2012). The highest perchlorate concentrations continue to be detected at MW-368M1 and M2. The conceptual understanding of this portion of the plume is that a high concentration core has bifurcated above and below fine strata, resulting in a shallow zone and a deep zone. The shallow zone (above elevation -50 feet msl) is primarily defined by recent perchlorate levels up to 76.9 µg/L at MW-368M2 and does not extend as far to the west or north as MW-339M2 (cross gradient to the west), MW-335M2 (downgradient and cross gradient to the west), or in shallow profile samples at J2MW-01 (downgradient).

The deep zone (deeper than -65 feet msl), showed a decrease in concentration from 70.8 µg/L in MW-368M1, (April 2008) to 45.0 µg/L (August 2012) and appears to be wider than the shallow zone, with perchlorate concentrations recently reported at 18.2 µg/L in MW-335M1 (March 2010). Concentrations in MW-335M1 have since declined to 0.21 µg/L in August 2012. The higher concentrations (above 15 µg/L) do extend to well J2MW-01M2, where perchlorate was detected at 17.4 µg/L (August 2012). This well is located adjacent to the deeper of the two screens of extraction well J2EW0005. The deeper zone appears to be beneath some low-hydraulic-conductivity units observed from approximately -45 feet msl to -65 feet msl at a number of locations in the middle of the plume (MW-368, J2MW-01, MW-335 and MW-339). The previous conceptualization of the lithology has been revised based on new boring results and the hydraulic start-up data (ECC 2010). One screen was placed at -28 to -39 feet msl and one screen from -68 to -82 feet msl to effectively capture the shallow and deep portions of the J-2 Range eastern plume.

The downgradient portion of the main perchlorate lobe thins considerably to approximately -90 to -110 feet msl in the vicinity of J2MW-04M1, where profile results did not detect perchlorate above the M1 screen, although the M1 screen, itself showed a slight increase from 2.15 µg/L to 2.7 µg/L between February 2009 and August 2012. Recent results from downgradient well MW-393M2 were reported at 0.03 µg/L (August 2012). These wells are screened from -52.7 to -62.7 feet msl and -61.5 to -71.5 msl, respectively.

Perchlorate concentrations continued to diminish at MW-319M1 in the southeastern lobe, going from a historic high of 1.8 µg/L in October 2005 to 0.29 µg/L in August 2012 (Figures 3-6 and 3-9) (Appendix D). These observations support the conceptual understanding of this lobe of the plume as narrow, vertically thin, and consisting of low concentrations.

Perchlorate concentrations in the eastern lobe, defined by perchlorate detections at MW-310M1 also continue to decrease (Figures 3-6 and 3-9) with the most recent concentration being 0.73 µg/L (August 2012). Concentrations in well MW-215M2 that define the northern edge of this lobe have increased from 1.8 µg/L (April 2008) to 5.3 µg/L (August 2012). This lobe is also narrow, vertically thin, and consisting of lower concentrations than the main lobe.

There have been no detections of perchlorate in monitoring wells in the western lobe above 2 µg/L since 2005. Samples collected from MW-366M3/M2 have been trace to ND since September 2006 and October 2007, respectively. Concentrations have been stable in MW-366M1 with a concentration reported at or near 1 µg/L since September 2012. There are also no significant perchlorate detections in downgradient monitoring wells (MW-381M1 and MW-381M2), since samples were first collected at these wells in August 2005. These results likely indicate that the lobe has naturally attenuated to concentrations below 2 µg/L, although a small area of concentrations above 2 µg/L, based on migrated data from 2005, has been retained in the plume depiction on Figure 3-1. Concentrations of perchlorate also continue at trace levels in well MW-388M2 located upgradient of MW-366.

RDX

The main body of the J-2 Range eastern RDX plume (above 0.6 µg/L), is approximately 5,800 feet long and up to approximately 1,150 feet wide at its widest point (Figures 2-10, 2-13, 2-14 and 2-15). The main body of the plume, as defined by RDX concentrations above 2 µg/L, is approximately 3,000 feet long and up to approximately 900 feet wide.

The core of the RDX plume is coincident with the shallower portion of the core of the perchlorate plume at approximately 40 feet msl and centered at MW-368. However, just downgradient of the core, at J2MW-04, the RDX plume is deeper and thicker than previously conceptualized with detections from approximately -75 to approximately -135 feet msl. The maximum monitoring well concentration in the plume has increased slightly to a maximum of 11.6 µg/L (MW-368M2, August 2012).

The western RDX lobe of the J-2 Range eastern plume is no longer depicted due to decreasing concentrations and sporadic detections. The western RDX lobe was based on detections at MW-366M2 and MW-388M2. However, RDX has not been detected at MW-366M2 since 2005 and the last detection at MW-388M2 was in 2007. RDX was detected at the deeper screen MW-366M1 (0.244 µg/L) for the first time in August 2009 but has been ND since.

The isolated, downgradient detection at MW-399 persisted through 2010 but was ND in 2011 and 2012 (Figure 3-10).

RDX concentrations in the upgradient portion of the plume have deceased to below 0.6 µg/L in two wells located beneath the source area: MW-307M3 and MW-228M2S. These results indicate there is very little mass continuing to leach from the source areas that contributed to the main lobe of the RDX plume. Downgradient of the source area, concentrations in MW-321M2 have also been below 0.6 µg/L since September 2009. Concentrations in J2MW-05M1/M2 have been nondetect since the first sampling round in September 2009. This well is located adjacent to extraction well J2EW0004 (Figures 2-12, 3-10).

In the middle of the plume, concentrations remained stable or decreased slightly in wells either above or below the low hydraulic conductivity units located near J2EW0005. RDX concentrations at MW-368M2, were little unchanged (13.8 µg/L to 17.6 µg/L from February 2009 to August 2012 but have risen from 0.83 µg/L to 5.9 µg/L in MW-368M1 between April 2008 and August 2012. In MW-335M1 concentrations have dropped to below 0.6 µg/L since September 2009. However, at MW-324M1M2 on the eastern margin of the plume at Wood Road, RDX concentrations dipped below 1 µg/L in 2009 and 2010 but have since rebounded to 1.6 µg/L in 2012. Upgradient well MW-215M2 has seen RDX concentrations between 2 and 3 µg/L since 2002 (Figure 3-10). In J2MW-01M2 (adjacent to the deeper screen at J2EW0005), concentrations have fluctuated from 1.1 µg/L to 3.5 µg/L since September 2009. This likely represents an effect of pumping at the extraction well, as profile results from this sample interval had a maximum detection of 0.36 µg/L. These results indicate the RDX plume is narrowing slightly at the edges and vertically as contaminated groundwater is being drawn into the extraction well.

In the downgradient portion of the plume, results from J2MW-04M2 have always been ND and have been ND since October 2008 in MW-393M1/M2. At MW-351M2, RDX concentrations have been ND since September 2009. The data indicates that the shallow RDX plume may be discontinuous in the area of J2MW-04M2 and the downgradient extraction well J2EW0006. The discontinuous nature of the plume may be a result of intermittent source releases.

RDX was detected deeper than previously conceptualized at J2MW-04M1 (from -78 to -138 feet msl) at concentrations up to 4.3 µg/L in borehole profile samples. Recent results from this well show a steady decline in concentration of RDX from 4.0 µg/L and 3.9 µg/L in samples collected in September 2009 and March 2010, to 1.2 µg/L in 2012 (Figure 2-12). These deeper detections were not part of the previous conceptualization because the deepest RDX detection previously was -90 feet msl at MW-351. Results from other borehole profiles and monitoring well samples from approximately -90 to -129 feet msl, around J2MW-04 (J2MW-01, MW-393M1, MW-351M1, and MW-354M1), were ND, indicating these deep detections of RDX were not laterally continuous.

An RDX concentration of 0.24 µg/L in downgradient well MW-436M2 in August 2012 is the first detection at this location. The RDX concentrations in the isolated lobe downgradient of the main lobe, continue to decrease to 0.33 µg/L (October 2008) and 0.335J µg/L (September 2009). These results are consistent with the previous conceptualization of this zone of contamination.

3.2.3 Other Compounds

Concentrations for all groundwater compounds are presented in Appendix C for profile samples and Appendix D for monitoring well samples (2007 to 2012). In addition to perchlorate and RDX, other compounds have been detected in the J-2 Range groundwater study area. The following explosive compounds were detected in the J-2 Range northern plume: 1,3-dinitrobenzene, 2,4,6-trinitrotoluene, 2,4-dinitrotoluene, 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, and octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX). All of the detections of other explosives in monitoring well samples occurred in monitoring wells located in the source area (MW-130S, MW-234M1,M2) or in the upgradient portion of the plume (MW-289M1,M2). The detects were low-level (generally below 10 µg/L) and did not exceed regulatory levels (i.e., maximum contaminant levels [MCLs], MMCLs, and HAs).

Profile samples were collected from one location (MW-519) in 2009 and submitted for NDMA analysis by Method 1625. There were two detects of NDMA in the borehole. NDMA was detected at 0.8 nanograms per liter (ng/L) (-2.64 feet msl) and at 2 ng/L (-88.64 feet msl). The Tapwater RSL for NDMA is 4.2×10^{-4} µg/L. However, these (and other) profile results were not included in the Risk Screening.

Compounds detected in the J-2 Range eastern plume, other than RDX and perchlorate, include the explosive compounds HMX, 2-amino-4,6-dinitrotoluene, nitroglycerin and pentaerythritol tetranitrate (PETN), and the VOC compounds chloroform and chloromethane. The detections of other explosive compounds were low-level (maximum of 13 µg/L) and have did not exceed any regulatory levels (i.e., maximum contaminant levels [MCLs], MMCLs, and HAs). Chloromethane is likely a laboratory artifact and not indicative of groundwater quality, and chloroform occurs naturally in the groundwater in the Sagamore Lens.

3.2.4 Water Quality Parameters

Water quality parameters were measured at existing and newly installed monitoring wells located within the J-2 Range groundwater study area during sampling events from May 9, 2006 to December 31, 2009 (Appendix E). The ranges and averages were similar to previous results. The range of groundwater water quality parameters are as follows: temperature ranged from

5.33 to 20.7 degrees Celsius (^{o}C) with a mean of 10.78^{o}C; dissolved oxygen (DO) ranged from 0 to 14.5 milligrams per liter (mg/L) with a mean of 10.13 mg/L; oxidation-reduction potential (ORP) ranged from –101.3 to 660.2 millivolts (mV) with a mean of 177 mV; specific conductance ranged from 28 to 210 microsiemens per centimeters (µS/cm) with a mean of 64 µS/cm; and pH [scale for measuring aqueous hydrogen ion (H^+) concentration] ranged from 4.45 to 8.23 standard units with a mean of 6.16.

3.2.5 Conclusions

The J-2 Range northern perchlorate plume is narrower than previously conceptualized and is becoming segmented due to the influence of the ETR system and natural attenuation. However, a significant amount of perchlorate mass remains in the plume upgradient of J2EW0001 as indicated by the recent dramatic increase and subsequent decrease in perchlorate concentrations at MW-585M2 and J2EW1-MW1-C, as well as elevated influent concentrations at this extraction well. The J-2 Range northern RDX plume is also smaller than previously characterized and is currently limited to the area upgradient of J2EW0001. The changes in J-2 Range northern plume characterizations do not affect the conceptual site model for how the plumes developed or how the plumes will migrate or attenuate in the future.

The overall extent of the J-2 Range eastern perchlorate and RDX plumes have not changed significantly since startup of the ETR systems in 2008; however, both plumes are beginning to display segmentation due to the effects of ETR system operations and natural attenuation. As with the J-2 Range northern plumes, these changes do not affect the conceptual site model for how the plumes developed or migrate.

These revisions to the groundwater plumes characterizations will be considered in the FS (Sections 8 through 11).

A long-term groundwater monitoring program at existing and new monitoring wells will be conducted to verify the effectiveness of the soil and UXO response; to ensure that groundwater modeling predictions regarding the reduction and migration of contamination are correct; and to ensure that any remaining contamination remains below risk-based levels.

As part of future groundwater monitoring investigations, a drilling program will be initiated in summer 2013 to document the extent of any contamination downgradient of J2EW003. Additional monitoring wells will also be installed at J-2 Range to assess the protectiveness of the downgradient water supplies, validate extraction well capture zones and for additional characterization purposes, including at locations downgradient of known source areas.

3.3 Source Characterization Activities

The source areas at the J-2 Range include both soil contamination and UXO (or munitions and explosives of concern [MEC]) that may be in or on the soil. Initial investigations of the J-2 Range focused on those features identified during a historical aerial photograph analysis of Camp Edwards. Additional range features were included in the investigation as range records became available. Information regarding range activities has also been obtained through interviews of current and former base employees and range workers and observations noted during site reconnaissance, as previously discussed in Section 2.2. However, available records generally lacked sufficient detail to allow focused soil characterization activities.

Since 1999 a variety of field investigation methods have been employed to help locate and characterize site features that have caused, or have the potential to cause, groundwater contamination. As discussed below, multiple lines of evidence have been developed, including geophysical and soil sampling data, to characterize the J-2 Range. The procedures and equipment used during these investigations are discussed in detail in Appendix G of this report. The following sections describe geophysical and soil sampling activities that have been conducted at the J-2 Range.

Soil characterization investigations in the J-2 Range commenced in 1997. During the period from July 1997 to May 2010, over 3,100 soil samples were collected at various depths from over 700 locations within the J-2 Range Study Area.

Samples were collected in accordance with the following work plans and project notes:

- *Draft Work Plan for Investigation of Munitions Survey Program Sites Phase 3* (USACE 2001)
- *Final Revised J-2 Range Supplemental Soil Workplan* (AMEC 2004), April
- *Final J-2 Range Supplemental Geophysical Anomaly Investigation Work Plan* (ECC 2005), January
- *J-2 Range Extension Area Reconnaissance – Summary and Recommendations* Project Note (ECC 2007), March
- *Final J-2 Range Extension Area Final Revised Field Investigation Approach* Project Note (ECC 2007), July
- *Final Engineering Detection Dogs Pilot Study Post-Survey Investigation Plan Project Note* (ECC 2007), October
- *Final J-2 Extension Additional Supplemental Soil and Groundwater Investigation* Project Note (ECC 2007), November

- *Final J-2 Range Supplemental Geophysical Anomaly Investigation Report – J-2 Range Priority 1 Grids Technical Memorandum* (ECC 2005), December
- *J-2 Range Rapid Response Action Completion of Work Report* (ECC 2007), July

Soils data collected pursuant to work plans and project notes dated after 2004 are formally presented for the first time in this remedial investigation report. Types of soil samples collected include soil boring samples, discrete soil samples, composite soil samples, and multiple increment soil samples. Soil samples associated with BIP activities have also been collected. The majority of the samples at J-2 Range were five-point composite samples collected from grids designed to represent a 22 feet by 22 feet area. Sampling points within the grid were placed equidistant from each other; one point in the center and four points offset from each of the grid corners to form an "X" pattern. Sampling depths were typically 0 to 0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1 feet below ground surface (bgs). Deeper depth samples or different grid dimensions may have been used depending on site features. Variations in grid dimensions, depths and/or number of composite points were defined in respective work plans. Soil samples were collected at magnetic anomalies, at proposed excavation areas, from the base of excavations, at specific features noted in site records, aerial photographs and site reconnaissance, and in support of BIP activities. Samples were also collected using systematic random sampling (using multiple increment samples) to characterize large geographic areas within the range. Typically, multiple increment soil samples were collected from a predetermined sample area following an approach outlined in CRREL TR-07-10. These sample areas corresponded with the grids established for the geophysical survey of the range (see Section 4.1.2). Post excavation 100-point multiple increment soil samples were collected from the 0 to 0.25 feet depth from each sample area following soil removal in the J-2 extension area. The number, location and depth of multiple increment samples were specified in various Project Notes. Grab samples were typically collected at locations with visible explosives, propellant and/or burn residue and submitted for explosives compounds and perchlorate analyses only. The circumstances and rationale for the collection of grab samples was designated in respective work plans.

Pre-BIP samples were collected from 0 to 0.25 feet depth around the UXO item combined as one sample and submitted for analysis. Post-BIP samples were collected following detonation from the bottom and sides of the BIP crater, combined and submitted for analysis.

Soil boring samples, obtained using a drill rig, were collected using stainless steel, split spoon samplers. The split spoon samplers were driven in accordance with the Standard Penetration Test (ASTM Method D1586-99) to designated sampling intervals. If required, a portion of the sample was collected for VOC analysis prior to homogenization of the soil. Sampling depths and analyses were specified at each sampling location and samples were typically collected every 5 to 10 feet from the ground surface to the top of the water table. In general, soil borings were used to characterize the vertical extent of contamination in those areas where surface soils were contaminated or where disposal activities were believed to have occurred.

Geophysical Surveys and Investigations

UXO discoveries have primarily been made in conjunction with ordnance clearance conducted in support of intrusive drilling, surface and subsurface soil sampling, and ground-based geophysical surveys. An initial ground-based geophysical survey was conducted at the J-2 Range in 2001 over an area of 28.7 acres approximating the historic maximum extent of vegetation clearance on the range.

The purpose of the geophysical survey was to produce a digital geophysical record of the ground surface that might help locate potential munitions disposal pits, and UXO items representing potential sources of contamination to the aquifer.

Site preparation included clearing the area of vegetation, conducting a UXO sweep, and establishing a reference grid throughout the investigation area. All UXO, UXO related materials, and debris encountered during the surface sweep were flagged and recorded on incident report forms. Following the surface sweep of the study area, EM-61 geophysical systems were used to survey the J-2 Range.

The geophysical investigations proceeded in a sequential manner. Each investigation used information collected during previous investigations to guide the next step of the process. The investigations typically focused on the geophysical anomalies with the highest potential to contain burial or disposal pits based on geophysical signals, field observations, witness interviews and accumulated site knowledge. Generally, the largest and/or most densely distributed anomalies (sometimes described as "polygons") were investigated during each phase, which resulted in smaller anomalies being investigated as the phases of investigation progressed and, ultimately, a very thorough evaluation of potential source areas.

Geophysical surveys and investigations were conducted at the J-2 Range as indicated in the table below.

Investigation Phase	Scope	Work Plan/Report
Air Magnetometer (AIRMAG) Surveys	Helicopter-mounted magnetometers of four large areas of MMR, including the J-2 Range.	*Draft AirMag Technology Evaluation Report* (Tetra Tech 2002)
Munitions Survey Program (MSP) Phase I	Ground-based geophysical survey (EM-61) of AIRMAG findings.	*MSP1 Final Report* (Tetra Tech 2003b)
MSP Phase III	Intrusive investigations of "polygons" identified in MSP Phase I as having the potential to contain burial pits or UXO items.	*Munitions Survey Project Phase 3 (MSP3)* *Final J-2 Range Polygon Investigation Report* (Tetra Tech 2003a)
Supplemental Geophysical Anomaly Investigations	Detailed reconnaissance and intrusive investigation of additional polygons/grids.	*Final J-2 Range Supplemental Geophysical Anomaly Investigation Work Plan* (ECC 2005) *Draft J-2 Range Supplemental Geophysical Anomaly Investigation Report – J-2 Range Priority I Grids* (ECC 2005)
Disposal Pit Analysis Investigation	Intrusive investigation of potential pit targets.	*Draft J-2 Range Supplemental Geophysical Anomaly Investigation Report – J-2 Range Priority 1 Grids Technical Memorandum* (ECC 2005)
Data Gap Assessment, QC Grid Investigations	EM-61 survey of previously cleared areas and intrusive investigations of select anomalies.	

Investigation Phase	Scope	Work Plan/Report
Data Gap Assessment, Detailed Reconnaissance Investigation	Detailed reconnaissance of areas of the range, and intrusive investigation of selected anomalies.	*Revised Reconnaissance for Assessment of Potential Data Gaps at the J-1 and J-2 Ranges* (ECC, Jan 2007) *Standard Operating Procedure for Detector-Aided Reconnaissance and Spatial Data Collection* (ECC, 22 May 2006b)
Data Gap Assessment, Aerial Photo Assessment	Intrusive investigations of previously disturbed areas identified in aerial photos.	*Revised Reconnaissance for Assessment of Potential Data Gaps at the J-1 and J-2 Ranges (*IAGWSO; Jan 2007) *Standard Operating Procedure for Detector-Aided Reconnaissance and Spatial Data Collection* (ECC, 22 May 2006b)
J-2 Range North Investigation – Detailed Reconnaissance	Detailed reconnaissance in data gap areas within the impact area of the J-2 Range; vegetation was cut and a geophysical survey was conducted over the full Area 4 footprint using an EM-61.	*Revised Reconnaissance for Assessment of Potential Data Gaps at the J-1 and J-2 Ranges Project Note* (ECC 2007)
J-2 Range North Investigation – Engineering Detection Dogs (EDD)	Intrusive investigation of areas identified by trained dogs as potentially containing explosives residues.	*Final Engineering Detection Dogs Pilot Study Post-Survey Investigation Plan* (ECC 2007)
J-2 Range North Investigation – Disposal Pit Discrimination Analysis Investigation	Intrusive investigation of targets meeting pit discrimination criteria in J-2 Area 4.	*Draft J-2 Range Supplemental Geophysical Anomaly Investigation Report - J-2 Range Priority 1 Grids Technical Memorandum (ECC 2005)*

Geophysical data and areas intrusively investigated are depicted graphically in characterization figures for each sub-area and summarized by phase in Table 3-5.

As indicated above, ground-based geophysical surveys included the application of EM-61 techniques. The EM-61 system operates by transmitting a pulsed electromagnetic field that then induces a secondary magnetic field in a buried metallic object (or metal-containing rock). The decay of the secondary magnetic field is measured and stored on a data logger for subsequent analysis. The EM-61 is typically used in one of two configurations. The KIMS system configuration consists of four 1-meter EM-61 coils lined up side by side and towed behind an ATV. This configuration is used in areas where the terrain is flat with few trees and can collect data in 4-meter-wide swaths. For areas that the KIMS system cannot access, one 1-meter EM-61 coil array is used and towed by hand. Both EM-61 configurations are towed along transects parallel to the axis of the reference grid laid out during the site preparation. Geophysical data is collected at some interval (e.g., 4 inches) along each transect and is stored in a data logger. Location data is collected via GPS. All data is downloaded into a computer at the end of the day for processing.

3.4 Source Characterization Findings

This section describes the various geophysical and soil characterization activities and results, lists the various removal actions that were conducted at the J-2 Range and presents a summary of the nature and extent of contamination/UXO at the range. To simplify the discussion, the range has been divided into four subareas (Areas 1 through 4) based largely on range features and the grid layout shown in Figure 2-4. These subareas were chosen based on historical range use, range features and the conceptual site model of the range.

Photo Aerial Assessment Investigation

A photo aerial assessment was conducted at the J-2 Range. Two locations in Area 1 (Location 10 and Location 14) were identified from site reconnaissance and historical aerial reviews. Location 10 contained munitions debris and metallic debris. Due to the size of Location 14, a geophysical survey was conducted and anomalies were selected for investigation.

One burial pit was identified within Location 14 and designated J2APA14-BLP-001. The following MEC items were discovered:

- Sixty-four M51 Series PD Fuzes, taken to the CDC, and determined to contain a small quantity of energetic material.
- Six M53 20mm armor piercing incendiary HE projectiles.
- Six pieces of raw explosives determined to be energetic.
- Four T330 30mm HE projectiles. Two 40mm frag balls determined to contain a small quantity of energetic material.
- One M73 35mm sub-caliber munitions determined to contain a small quantity of energetic material.
- One M43 81mm HE mortar.
- One M1 105mm cartridge case with raw propellant determined to contain energetic material.

Two additional locations, J2LOC14 Area 2 and J2LOC14 Area 3 were investigated and munitions debris and metallic debris were discovered. Individual targets were excavated in support of the investigation at Location 14. One MEC item, a M43 81mm HE mortar, was BIP.

3.4.1 N Range

Although not considered part of the J-2 Range based on the primary nature of the activities conducted there, soil samples associated with the adjacent N Range (Figure 3-12) are discussed in this section due to their proximity to Area 1. As part of the N Range MSP III investigation in August 2002, 13 anomalies were intrusively investigated. MEC items were discovered at Anomaly #7, which included 23 M72 66mm LAW launchers with possible live primers and 18 shock tubes for the 66mm LAW rocket as well as munitions debris and metallic debris. The MEC items were determined to contain a small quantity of energetic material. Also discovered at Anomaly #12 were 59 M29 3.5-inch Rockets with suspect M404 base detonating fuzes. These items were BIP and no explosives compounds or perchlorate were detected in the pre- and post-BIP samples.

A disposal pit containing munitions debris and metallic debris was discovered at Anomaly #3. The excavated soil (sample location SS04752-A) had a detection of TNT at 276 µg/Kg (Figure 3-13). SVOCs and metals were also detected. The excavation floor had no detections of explosives or perchlorate. These soils remain on-site and are evaluated in the risk screen (Section 6.0).

Soil samples were collected from four locations along the N Range firing line (SS165B, SS165C, SS165D, and SS165E). 2,4-DNT was detected in all the samples ranging from 24 µg/Kg to 1,000 µg/Kg (Figure 3-13). No other explosives or propellant compounds were detected. However, these samples were only analyzed for CL245.5 (mercury); CL200.7 (metals); and SW8270 (SVOCs). There were no analyses performed for SW8330 (explosives) or E314.0 (perchlorate).

Additional samples were collected from N Range during investigations conducted in 2000 and 2004. Overall, six propellant-related compounds (including di-n-butyl phthalate, n-nitrosodiphenylamine, 2-nitrodiphenylamine, 2,4-DNT, 2,6-DNT and n,n'-diethylcarbanilide) were detected in one or more of the 34 samples analyzed from the N Range firing line. The first two of these compounds were detected in more than half of the samples analyzed. The maximum concentrations of di-n-butyl phthalate and n-nitrosodiphenylamine were 1.4 mg/Kg and 1.3 mg/Kg, respectively. These maximum concentrations were all reported for surface samples from grid 165C. The maximum detected concentration of 2,4-DNT was 1.0 mg/Kg in a surface soil sample collected from grid 165B. Several additional SVOCs including a few PAHs were reported in samples from N Range. Twelve metals were detected in one or more samples at concentrations above their respective MMR background levels. The maximum reported concentration of lead was 31.1 mg/Kg. The N Range small arms range will be further evaluated as a component of the Small Arms Range Operable Unit (SAR OU).

3.4.2 Area 1 – Firing Points/Melt Pour Facility/Disposal Areas (Rows 10 to 17)

Area 1 is located in the southernmost portion of the J-2 Range (Figure 2-4). The Archive Search Report indicates that this area of the range had multiple uses including firing points, a melt/pour and loading area, and a staging and administrative area for munitions testing. The area also has an existing bunker (grid J12) to which access is restricted by a locked fence. The bunker is empty and not currently in use.

The following site features (Figure 3-12) are or were formerly located within Area 1:

- Melt/Pour Facility Area
- Fixed Firing Point 1 (FFP-1)
- Fixed Firing Point 2 (FFP-2)
- Drop Tower
- Loading/Conditioning/CONEX Area
- Latrine/Soil Pile

In addition, the following significant features were identified as a result of intrusive investigation of geophysical anomalies:

- Burial Pits/Disposal Areas: I12-BLP-001, I16-BLP-001, polygons 32-34, J16-BLP-001, J16-BLP-002, J16-BLP-003, H17-BLP-001.

Prior to the initial ground-based geophysical survey a surface sweep was conducted in Area 1. Thirteen T330 30mm HEI projectiles were found in grid M17. All 13 projectiles were damaged but not cracked or leaking when found and were identified as inert and moved to a safe holding area. Three additional T330mm HEI projectiles were found in this grid in 2006 and were BIP. For data presentation purposes, Area 1 is divided into two subareas, based on the conceptual site model presented in the Munitions Source Assessment (Appendix G). The area lying primarily within rows 10 to 14 contained the majority of the Melt/Pour Facility Area, the Drop Tower, the latrine, and a bunker surrounded by a chain link fence. Rows 15 to 17 contained a small building of the Melt/Pour Facility Area, FFP-1, FFP-2, and the Loading/Conditioning/CONEX Area. The investigation results for these subareas are discussed below and the analytical results for soils remaining in place are further evaluated in the risk screening (Section 6).

A total of 378 samples were collected from 83 locations in Area 1 from July 2000 through September 2008. In most cases, samples were collected from multiple depths at each location, resulting in a larger number of samples than actual sample locations. Additional details about soil samples collected around each feature within this subarea are discussed below and presented in Table 3-6. Table 3-7 summarizes analytical detections in soil that has already been excavated during various intrusive investigations, removal actions, or in conjunction with BIP activities. Table 3-8 summarizes analytical detections for all soil samples, which represent current in-situ site conditions. The complete database for all soil analytical results collected through 2008 is included in Appendix F. Soil sample locations as well as locations and descriptions of MEC items identified in the field are depicted on Figure 3-12. Figure 3-13 depicts current site conditions and includes chemical results boxes for samples with remaining explosives compounds or perchlorate detections. Munitions items were categorized based on their explosive characteristics. The categories developed include high explosive (HE), possible HE, Propellant/Energetic, Small Quantity Energetic, and Inert. Munitions items that were classified as HE were required to have positive identification for their main charges (e.g., lot number or post-BIP results indicative of HE). Items that were classified as “possible HE” were munitions items that were assumed to contain HE on initial discovery and were either transported to the CDC for detonation or BIP, where the actual presence of the HE was not conclusively established or was not recorded. Items classified as Propellant/Energetic include raw propellant, chunk explosives or bulk explosives. Items classified as Small Quantity Energetic were MEC items that contained small amounts of energetic materials in one or more components (fuzes, detonators spotting charges). Items classified as inert were munitions items that were considered to be HE as a safety precaution but post-BIP or CDC results indicated that the item was inert.

3.4.2.1 Grid Rows H10 to M14

A number of range features were located in rows H10 to M14, which encompasses the southern end of Area 1. These features include the bunker, latrine, and former structures functioning as a Melt/Pour Facility and support buildings. In addition, a number of geophysical and intrusive investigations of anomalies were conducted within these rows and are discussed below.

A Drop Tower was possibly located approximately 100 feet southwest of the Melt/Pour Facility. Though there is no confirmation of a structure at this location, the presence of berms suggests that explosives may have been handled at this location. No MEC items were reported within this area. Composite samples were collected from four sample locations (101T, 101TB, 101TC and 101TD). Explosives compounds were not detected (Figure 3-13). Metals and SVOCS were detected and are evaluated in the risk screen (Section 6.0).

A former latrine was located in grid J11. The latrine structure itself was removed during the RRA in July 2005 and the latrine pit was backfilled with clean fill, as further discussed in the *J-2 RRA Completion of Work Report* (ECC 2007). No MEC items were reported within the Latrine/Soil Pile area. An impermeable membrane was also placed over the bottom of the pit prior to backfilling to demark the base of the excavation.

Four discrete samples were collected from one location at the bottom of the latrine for perchlorate and explosives compounds analysis. Perchlorate was not detected in any of the samples and the only explosives compound detected was 2,4-DNT at 1,200 µg/Kg (sample location SS101Q) by EPA Method 8270 (Figure 3-13). It is noted that 2,4 DNT was detected at only 170 µg/Kg in the same sample as analyzed by EPA Method 8330. This detection, as well as detections of SVOCs and pesticide compounds, remain in-place and are evaluated in the risk screen (Section 6.0). Eleven soil samples were also collected from a soil pile located just to the northeast of the latrine (SS101R). There were no explosives compounds detected in these samples.

Intrusive investigation of numerous geophysical anomalies within rows H10 to M14 resulted in the discovery of several disposal pits. A burial pit comprised of three polygons (polygon 32-34) was discovered directly northeast of the latrine in grid K11. MEC items found in polygon 32 included one explosive bolt and three 66mm LAW rocket fuzes. The explosive bolt was transported to CDC and determined to contain a small quantity of energetic material. The 66mm LAW rocket fuzes were blown-in-place and determined to be inert based on post-BIP observations by UXO technicians. All other munitions items were determined to be inert and were blown-in-place. MSP burial pit soil samples were collected from the excavated soil (J2.F.T32.XC1.1.0) and from the excavation bottom (J2.F.T32>XC1.2.0) from polygon 32. All samples were submitted for the following analyses: explosives, perchlorate, SVOCs, VOCs, PCNs and TAL metals. Explosives compounds, perchlorate and PCNs were non-detect in all samples. Estimated low levels (i.e., below risk screening levels) of acetone, bis(2-ethylhexyl)phthalate, di-n-butyl phthalate, PAHs, and select metals were detected and are evaluated in the risk screen. The excavated soils remain on-site.

MEC items found in polygon 33 included one 40mm projectile, four explosive bolts, twelve 3.5-inch rockets, one unfuzed 66mm LAW rocket, and seven 66mm LAW rocket fuzes. The 40mm projectile was transported to the CDC and was presumed HE. The explosive bolts were transported to the CDC and determined to contain small quantities of energetic material. The 66mm LAW rocket fuzes were blown-in-place and determined to be inert based on post-BIP observations by UXO technicians. All other munitions-related items were determined to be inert and were designated as scrap. Non-OE scrap included empty metal cans, an aluminum sheet, and an empty 55-gallon drum.

Soil samples were collected from the excavated soil piles in polygon 33 (J2.F.T32.XC1.1.0/ J2.F.T33.XC1.1.0) and from the excavation pit bottom in polygon 33 (J2.F.T32.XC1.2.0/ J2.F.T33.XC1.2.0). All samples were submitted for the same analyses as for polygon 32 discussed above. Explosives compounds, perchlorate and PCNs were non-detect in all samples. Estimated low levels of acetone, bis(2-ethylhexyl)phthalate, di-n-butyl phthalate, PAHs, and select metals were detected and are evaluated in the risk screen. The excavated soils remain on-site.

Only scrap/debris were discovered in polygon 34. Non-OE scrap included empty metal cans, an aluminum plate, an empty gasoline container, an empty 55-gallon drum, an empty 1-gallon glass container, and one crushed and flattened 1-gallon paint can containing paint. No sampling was conducted in this polygon as no MEC items were discovered.

Polygon 35 was located in grid K12 and contained steel wire, copper communication wire, and a crushed and empty 55-gallon drum. No soil samples were collected from this area because no unusual soil characteristics were observed. No MEC items were reported in this area.

Polygons 26-31 within grids H/I13 and H/I14 contained primarily scrap. Items identified included a 55-gallon drum filled with 56 steel plates, metal-framed sheets of aluminum, an empty 20-gallon drum and 55-gallon drums and drum parts, pipe, sheet metal, angle iron, steel cable, concrete pad, air conditioning unit, and one dummy and inert 3.5-inch rocket. No soil samples were collected from this area because no unusual soil characteristics were observed.

A disposal pit (I12-BLP-001, J2I12 Area 2) was identified in grid I12. Sixty-one unknown fuzes and six impulse cartridges were discovered to contain a small quantity of energetic material. Twenty-two T306 30mm projectiles were also discovered, taken to the CDC, and presumed to be HEI. Approximately 100 cubic yards of soil was excavated. Soil samples collected from the stockpile (SSJ2I2BLP001) had detections of RDX at 1,100 µg/Kg, HMX at 120 µg/Kg, and perchlorate at 0.84J µg/Kg (Table 3-13). The post-excavation sample was non-detect for explosives and had a perchlorate detection of 0.35 µg/Kg (Figure 3-13). These soils were transported by Global Remediation and disposed of off-site at an approved facility in spring 2008.

Seven cubic yards of soil was excavated from Location 35 in grid I13 during the investigation of two 55-gallon drums. No MEC items and only scattered subsurface pieces of scrap metal were discovered at that location. The waste characterization sample was non-detect for explosives compounds and perchlorate, but had low-level detections of a number of PAH compounds. However, the PAHs benzo(a)anthracene, benzo(a)pyrene and benzo(b)fluoranthene were detected at elevated concentrations (1,100 µg/Kg, 880 µg/Kg and 1500 µg/Kg, respectively). These soils were disposed off-site at an approved facility.

A few of the anomalies investigated contained munitions debris and/or metallic debris. These locations include but are not limited to Location 2 (grid J13), Location 4 (grid I14), Location 10 (grid L14), Location 11 (grid J13), Location 14 (grid K14), Location 19 (grid J14), Location 23 (grid K13), and Location 24 (grid L14).

Supplemental geophysical surveys were also performed in Area 1 as quality control measures within selected grids to determine the effectiveness of previous munitions investigations and soil removal actions. MEC items were discovered in the following locations:

- J2H13 Area 1 in grid H13: Three inert M28 3.5-inch HEAT rockets with live fuzes were discovered, BIP, and determined to contain small quantities of energetic material.
- J2K11 Area 1 in grid K11: Two T324 37mm projectiles were found and presumed to be HE. In J2K11 Area 3, a booster cup with explosive filler was found and determined to be energetic.

Munitions debris and/or metallic debris was found at J2H12 Area 1, J2H13 Area 1, J2I11 Area 1, J2I11 Area 2, J2I12 Area 1, J2I13 Area 1, J2I13 Area 2, J2I14 Area 1, J2K11 Area 1, and J2K11 Area 2.

3.4.2.2 Grid Rows H15 to M17

A number of range features were located in rows H15 to M17, which encompass the northern end of Area 1. These features include the loading/conditioning/CONEX area, FFP-1 and FFP-2, melt/pour facility area, and former structures housing support activities. In addition, a number of geophysical and intrusive investigations of anomalies were conducted within these rows and are discussed below.

<u>Loading/Conditioning/CONEX Area</u>

The loading building was used for loading (assembly) of propellant into casings for 105mm projectiles and LAW rockets. The conditioning building was used for the hot and cold conditioning of propellants and the CONEX was used to store explosives such as blasting caps (USACE 1999a,b). No MEC items were discovered within this area. A total of 12 soil samples were collected from four sample locations (SS101UA - SS101UD) (Figure 3-12). There were no explosives compounds or perchlorate detected in the samples, except for a perchlorate detection of 3.25 µg/Kg from sample location SS101UD (Figure 3-13). This detection is evaluated in the risk screen (Section 6.0).

<u>Fixed Firing Point 1 (FFP-1)</u>

FFP-1 is located at grid J15. No MEC items were reported within this area. Soil samples were collected from five composite sample locations (SS101BA, SS101BB-BE). Soil samples were also collected during the installation of well MW-121. 2,4 DNT was detected at sample location SS101BA at 56 µg/Kg (Figure 3-13, Table 3-8). No other explosives compounds were detected. Low concentrations of SVOCs, pesticides and metals were detected sporadically and are evaluated in the risk screen (Section 6.0).

<u>Fixed Firing Point 2 (FFP-2)</u>

FFP-2 is located at grid K15. No MEC items were reported within this area. One composite and five discrete soil samples were collected from sample location SS101CA. No explosives compounds were detected in these samples (Figure 3-12). SVOCs were also detected in these samples and are evaluated in the risk screen (Section 6.0).

<u>Melt/Pour Facility Area</u>

The Melt/Pour Facility was allegedly used for mixing and loading of munitions to support testing activities. Reportedly, OCTOL, RDX and Composition B were mixed and loaded at this facility. Fragmentation tests were also allegedly conducted at this location using RDX. No MEC items were recorded within the Melt/Pour Facility area. Soil samples were collected from three composite sample locations (SS101AA, SS101AB, and SS101AC) and six discrete sample locations (SS101A1-SS101A6) (Figure 3-12). Eleven soil samples were also collected from the MW-122 boring (BH-29) located adjacent to the Melt/Pour Facility. Explosives compounds were detected in samples collected from locations 101A1 (RDX at 220 µg/Kg, TNT at 360 µg/Kg), 101AB (2,4 DNT at 270 µg/Kg), and BH-29 (TNT at 150 µg/Kg) (Figure 3-13; Table 3-8). These detections remain in place will be evaluated in the risk screen (Section 6).

Samples 101A1-A4 and 101A6 were also collected for dye analysis. One dye, benzanthrone that is insoluble in water, was detected in shallow surface soils ranging from 23 to 40 µg/Kg. The significance of these detections is evaluated in the risk screen (Section 6.0).

Prior to anomaly investigation, soil samples were collected to characterize select areas. Standard five-point composite soil samples were collected at two locations at depths of

0-3 inches, 3-6 inches, and 6-12 inches below ground surface (bgs) in grids H15 and I16 and analyzed for perchlorate and explosives. Results from these samples were ND. Samples were collected in April 2005 from locations SSJ2SG001 (grid I16) and SSJ2SG002 (grid H15) prior to the supplemental geophysical investigation.

Intrusive investigation of numerous geophysical anomalies also resulted in the discovery of several disposal pits. A burial pit (I16-BLP-001) was discovered in grid I16. Two 66mm LAW warheads were found, presumed to be HE and taken to the CDC. Approximately 9 lbs of M7 propellant was also found. One unknown cartridge actuated device and four unknown detonators were determined to contain a small quantity of energetic material. One T330 30mm HEI projectile was also discovered. Munitions debris and metallic debris were also encountered at I16-BLP-001. A summary of items found is provided in Table 1 of Appendix G. Approximately 100 cubic yards of soil was excavated. Waste characterization samples collected from the stockpiled soils (SSJ2I16BLP001) had detections of RDX at 540 µg/Kg, and perchlorate at 10.4 µg/Kg, (Table 3-13). These soils were transported by Global Remediation and disposed of off-site at an approved facility in spring 2008. The sample collected from the excavation bottom had no detections of explosives compounds or perchlorate.

Three disposal pits (J16-BLP-001, J16-BLP-002, and J16-BLP-003) were identified in grid J16. These three disposal pits are in very close proximity to each other, and so are discussed together. In J16-BLP-001, four M720 60mm mortars were found and determined to be HE. One PD Fuze was determined to contain a small quantity of energetic material. In J16-BLP-002, one 3.5-inch rocket motor was taken to the CDC and determined to contain a small quantity of energetic material. In J16-BLP-003, thirty 60mm mortars and six M775 PD fuzes were determined to contain a small quantity of energetic material and taken to the CDC. Approximately five cubic yards of soil was excavated from J16-BLP-001. Soils excavated from the other two disposal pits (J16-BLP-002 and J16-BLP-003) were combined with the soil excavated from J16-BLP-001 and the stockpile was sampled. There were no explosives detected, but perchlorate was detected at 4.5 µg/Kg (Table 3-13). In addition, PAHs were detected at elevated concentrations with the highest detection being fluoranthene at 108,000 µg/Kg. These soils were disposed off-site at an approved facility. The excavation bottom sample had no detections of explosives compounds or perchlorate.

A disposal pit (H17-BLP-001) was identified in grid H17. One M18 66mm HE LAW rocket and one T324 37mm HE projectile were found. One explosive bolt, fourteen 30mm live primer cartridges and two 3.5-inch rocket motors were determined to contain a small quantity of energetic material and taken to the CDC. Samples collected from the excavated soils (SSJ2H17BLP001) had no detections of explosives compounds or perchlorate and, therefore, the soil stockpile remains on the range (Figure 3-13). The excavation bottom sample (SS17BLP) had no detections of explosives or perchlorate (Figure 3-13).

A few of the anomalies investigated contained solitary or multiple surface (not buried) munitions. Two 30mm HEI projectiles were discovered in grid J16 and were taken to the CDC. In addition, one booster fuze and one mortar primer tube were discovered, taken to the CDC, and determined to be inert. Munitions debris and/or metallic debris were found at Location 1 (grid L17), Location 3 (grid M15), Location 7 (grid K17), Location 9 (grid K17), Location 12 (grid K15), Location 17 (grid L16), and Location 31 (grid J15).

Supplemental geophysical surveys were performed as quality control measures within selected grids to determine the effectiveness of previous munitions investigations and removals. MEC items were discovered in J2J16 Area 1. Seventy-one M935 PD fuzes were found and taken to the CDC. Each contained a small quantity of energetic material.

Munitions debris and/or metallic debris were found at J2H15 Area 1, J2H17 Area 1, J2I16 Area 1, J2I16 Area 2, and J2I16 Area 3.

3.4.2.3 Area 1 BIP-Related Sampling

A total of 66 pre-BIP, post-BIP, supplemental and post excavation samples were collected from six locations associated with BIP activities in Area 1. BIP sample locations, sample identification, collection date, sample depths, and laboratory analyses associated with this area of the range are listed in Table 3-6. Contaminated soils generated as a result of BIP activities were excavated as required under the BIP management program. Table 3-7 contains analytical detections for those soils excavated under the BIP management program.

Pre and post-BIP sample results were evaluated in annual BIP reports to determine whether further actions were necessary. No further action was required at two locations; SS11061-A in polygon 12 and Target 32; analytical results from pre and post-BIP sample collected from these locations were below action levels. Further action was required at four locations where results exceeded action levels; cadmium at OG071100-02, explosives at SS04181-A, explosives, perchlorate and cadmium at SSJ2H13001 and explosives and perchlorate at SSJ2M17001. Supplemental samples were collected at all locations. There were no action level exceedances in any of the supplemental samples and the surrounding 5-foot by 5-foot area at each location was excavated to a depth of 6 inches. Post-excavation sample results were either non-detect or less than action levels.

3.4.2.4 Area 1 Source Characterization Conclusions

Area 1 served primarily administrative functions. Buildings formerly present included the Melt/Pour facility, a framed shed of unknown use, a one-story concrete block building and attached framed shed reportedly used for ordnance assembly, two single-story framed buildings reportedly used for vehicle maintenance and office space, three buildings of unknown use, a tower, bunker, large concrete pad, construction trailer, pump house for a water supply well, a former ammunition supply magazine with a fenced enclosure, and a latrine. The majority of structures were removed in 1986 during general demobilization/cleanup of the range.

The conceptual site model of munitions use in J-2 Range, Area 1 was developed from range characteristics, range records, review of aerial photographs, and intrusive investigation finds. The development of the conceptual site model is presented in Appendix G. The available information suggests that one specific activity occurred within grids H, I, J, K, L, M in rows 10, 11, 12, 13, 14, 15, 16 and 17 and was indicative of contractor testing and general disposal. Firing positions did exist in grids J15 and K15.

Burial pits and/or disposal areas were found in grids K11, I12, I16, J16, and H17. The majority of the MEC items in all pits were found to be small quantity energetic items (with the exception of I16-BLP-001 where 9 pounds of M7 propellant were discovered). None of the disposal locations were identified as burn pits and there are no known impact or target locations within Area 1.

In February 2013, an additional 13 anomalies were surveyed. Eleven anomalies contained surface debris in grids K12 (one anomaly with wire and aluminum paper), I13 (one anomaly with a buttress), J14 (three anomalies containing aluminum sheeting, a concrete pad with metal reinforcement and building debris, and a concrete block), K14 (one anomaly with a concrete block), K15 (one anomaly with aluminum sheeting.), M15 (two anomalies with a concrete pad with metal reinforcement and wire, stakes and building debris), and K16 (one anomaly with a barbed wire fence stake). One anomaly in grid K15 was identified as a “No Find.” The remaining two anomalies, one each in grids I13 and K16, were located on a berm which will require vegetation removal to gain access to the anomaly location. No MEC items were found in any of these grids.

Area 1 had the lowest percentage of MEC items of the J-2 Range subareas and is considered up-range. A significant reduction in overall MEC has been accomplished through investigation and soil removal actions. The highest percentage of MEC items discovered was from the burial pits that were found in five grid locations. As indicated above, the majority of the MEC items in all burial pits were found to be small quantity energetic items. The exception to this is the burial pit in grid I16 where the following HE items were discovered as listed in Table 1 of Appendix G: nine pounds of M7 propellant, one 30mm projectile, and one 66mm rocket. It is likely that additional T330 30mm HEI projectiles may be located in the northern portion of Area 1, within grid M17. Large residual anomalies are associated with cultural features and metallic structures from contractor testing (Figure 3-12). Isolated medium to small sized geophysical anomalies still remain on the range and it is likely that they are due to fragmentation, metallic debris, or individual intact munitions that could be either inert or HE. Items that could remain in Area 1 containing HE or a small quantity of energetic include M72 66mm LAW rockets, 60mm mortars, M43 81mm mortars, M28 3.5-inch rockets, T324 37mm projectiles, T330 30mm projectiles, and fuzes.

3.4.3 Area 2 – Firing Points/Testing/Disposal Area (Rows 15 to 29)

Area 2 is the largest of the four J-2 Range areas and is situated in a generally southeast to northwest direction (Figure 2-4). This area was extensively evaluated in a series of detailed geophysical, soil sampling and intrusive investigations commencing in the year 2000. The following site features are, or were, formerly located within this sub-area:

- Brick-lined Pit 1
- Berm 2
- Disposal Area 1
- Mortar Position
- Berm 3
- Range Road Burn Area (RRBA)
- Twin Berms
- Fixed Firing Point 3 (FFP-3)
- Fixed Firing Point 4 (FFP-4)
- Fixed Firing Point 5 (FFP-5)

The following significant features were identified in Area 2 as a result of intrusive investigation of geophysical anomalies:

- **Impact Areas:** Inert mortar impact areas were identified in locations known as polygons 7, 9, and 11 in the central portion of Area 2.
- **Disposal Areas:** Four locations identified as polygons 6B, 8, 13, and 14B contained only scrap metal.

- **Burial Pits:** A total of eleven burial pits (polygons 6A, 6C, 6D, 10, 14A, 14C, 15A, and 16, locations 8 (M20-BLP-001) and 28 (M20-BLP-002), and J2L19 Area 2 (L19-BLP-001) were identified in three general areas. The burial pits are located in portions of grids M19, M20, N19, O22, O23, P20, P21, P22, P23 and P24.

Prior to the initial ground-based geophysical survey, a surface sweep was conducted in Area 2. A list of results from representative grids is presented below (Tetra Tech 2003a).

Grid	Item	Quantity
M21, M20, M19, N21 and N20	T330 30mm HEI projectiles	107
	M306 57mm inert projectiles	80
	M306 57mm inert projectiles	4
	M306 57mm unfuzed HE projectiles	10
O29	40mm HE grenade	1
	Pyrotechnic residue (small quantity energetic)	NA
O28	T330 30mm HEI projectile	1
	57mm inert training practice projectile	1
P26	3.5 inch unfired rocket	1
M26	T330 30mm HEI projectile	2
	57mm HE unfuzed projectile	25
	57mm inert training practice projectile	13
M25	M306 57mm inert projectiles	5
N24	M404 3.5 inch HEAT HE rocket	1
	M49 60mm inert mortars (with possible live fuzing)	34
M24	M49 60mm mortars (unfuzed)	2
N23	81mm M43 Practice/Unfuzed mortar	1
	M49 60mm HE mortar	1
	M72 60mm HE mortar	1
	T330 30mm HEI projectile	1
M23	57mm inert projectiles	4
M22	57mm inert projectiles	3
	57mm unfuzed HE projectile	1
	Fuze, Practice grenade (small quantity energetic)	1
O20	57mm unfuzed HE projectile	51
	T330 30mm HEI projectile	1
O19	M374 81mm HE mortar	1
O17	T330 30mm HEI projectile	1
L29	M72 66mm LAW HE rocket	2
	90mm inert projectile (prototype)	1
	105mm canister flare inert	1
	M306 57mm HE projectile	3
	M720 60mm HE mortars	1

For data presentation purposes, Area 2 is divided into four subareas, based on the conceptual site model presented in the Munitions Source Assessment (Appendix G). The area lying primarily within Rows 15 to 17 contained firing positions, and an impact area for HE rounds, Rows 18 through 21 contained a MEC Disposal Area and impact area for HE rounds, Rows 22 through 26 primarily encompass a general disposal area, and Rows 27 to 29 contained a disposal pit. The investigation results for these subareas are discussed below and the analytical results for soils remaining in place are further evaluated in the risk screening (Section 6).

A total of 1,803 samples were collected from 354 locations in Area 2 from February 1999 through September 2009. At most locations, composite samples were collected from three depths (0 to 0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1-foot bgs). Samples collected for VOC analysis were discrete samples. Additional details about soil samples collected around each feature within Area 2 are discussed below and presented in Table 3-9. Table 3-10 summarizes analytical detections in soils that have already been excavated during various intrusive investigations, removal actions, or in conjunction with BIP activities. Table 3-11 summarizes analytical detections for all soil samples, which represent current in-situ site conditions. Soil sample locations, as well as locations and descriptions of MEC items identified in the field, are depicted in Figure 3-14. Figure 3-15 depicts MIS sampling grids and results. Figure 3-16 shows areas excavated during RRA activities, and Figure 3-17 depicts current site conditions and includes chemical results boxes for samples with explosives compounds or perchlorate detections. The complete analytical data set for all soil results collected through 2009 is included in Appendix F.

3.4.3.1 Grid Rows N15 to P17

A number of range features were located in rows N15 to P17, which encompass the southern end of Area 2. These features include Fixed Firing Points 3, 4 and 5, the Twin Berms, the Range Road Burn Area (RRBA), and a Mortar Position (Figure 2-4). In addition, a number of geophysical and intrusive investigations of anomalies were conducted within these rows and are discussed below.

<u>Fixed Firing Point 3 (FFP-3) (Grid N15)</u>

FFP-3 is located within rows N15 to P17 at the southern end of the J-2 Range immediately adjacent to the southern end of the RRBA (Figure 2-4). FFP-3 was reported to be one of the main firing points for tests and a location where excess propellant was burned.

During initial sampling efforts at FFP-3 conducted from 2000-2002, a total of 30 samples were collected from seven sample locations SS101DA, SS101DB, SS101DC, SS101DE, SS101DF, SS101DG and SS101DH (Figure 3-14). 2,4-Dinitrotoluene was detected in one sample (SS101DC) at 240 µg/Kg. Perchlorate was detected at a low level of 4.25J µg/Kg in the field duplicate sample collected from location SS101DH but not in the corresponding original sample. SVOCs, VOCs, PCNs and metals were also detected. Samples from three locations (SS101DE, SS101DF, and SS101DG) were analyzed for dioxin/furans analysis. Dioxin/furan congeners were detected in all samples. Six additional samples were collected at two locations in 2004: 101DI and 101DJ (SS15164 and SS15165) and analyzed for explosives compounds and perchlorate; all results were non-detect.

Monitoring well MW-116 was advanced within FFP-3. A total of 13 soil-boring samples were collected from the boring in August 2000. Five samples were analyzed for explosives compounds. Explosives compounds were not detected in any of the soil boring samples. Low levels of pesticides, VOCs, SVOCs and metals were detected in some samples.

In 2004, a Rapid Response Action (RRA) was conducted and 123 cubic yards of soil contaminated with explosives compounds were excavated from FFP-3 down to a depth of 1.5 feet (Figure 3-16). Post-excavation samples collected from locations SSJ2FFP3001 and SSJ2FFP3002 were non-detect for explosives compounds and perchlorate. No MEC items were reported during the excavation clearance. Excavated soils were thermally treated on-site.

Fixed Firing Point 4 (FFP-4) (Grid O14)

FFP-4 is located within rows N15 to P17 at the southern end of Area 2 to the immediate north of FFP-3 (Figure 2-4).

During initial investigations at FFP-4, a total of 47 soil samples were collected from 14 locations (SS101E and SS101EA-SS101EM [Table 3-11]) in the vicinity of the FFP-4 subareas (Figure 3-14). Explosives compounds were detected in five samples collected from five locations (SS101E, SS101EB, SS101EH, SS101EJ and SS101EM). Nitroglycerin was detected in three samples at a maximum concentration of 7,500 µg/Kg in the sample collected from location SS101EB; 2,4-DNT and RDX were also detected at low levels. Perchlorate was detected in nine samples collected from five locations (SS101EH, SS101EI, SS101EK, SS101EL and SS101EM) at concentrations ranging from 3.13 µg/Kg to 501 µg/Kg at location SS101EM (0.25 to 0.5 feet bgs). SVOCs, VOCs, PCNs and metals were also detected in some samples. Excavated soils were thermally treated on-site.

Based upon these investigation results, a total of 15 additional samples were collected at five locations 101EN-101ER in February 2004 (Loc_IDs SS15155, SS15167, SS15168, SS15169 and SS15170) (Figure 3-14). No explosives compounds or perchlorate were detected in any samples. Low levels of SVOCs were detected in some samples.

Soil contaminated with explosives compounds and perchlorate was excavated from three locations in the FFP-4 subarea during a RRA conducted in 2004. A total of 93 cubic yards of soil was removed to a depth of 1.5 feet surrounding sample locations SS101EL and SS101EM. Twenty-five cubic yards of soil was removed to a depth of 0.75 feet surrounding sample location SS101EJ, and 44 cubic yards of soil was removed to a depth of 1.5 feet surrounding sample location SS101EI (Figure 3-16). Four post-excavation samples were collected (SSJ2FFP4001-4004). All results were non-detect for explosives compounds and perchlorate. No MEC items were reported during the excavation clearance. Excavated soils were thermally treated on-site.

Fixed Firing Point 5 (FFP-5) (Grid P15)

FFP-5 is located immediately northeast of FFP-4 (Figure 2-4).

During investigations conducted in August 2000, a total of 18 samples were collected from one location (SS101FA) (Figure 3-14). Three composite samples were collected from three depths (0 to 0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1 feet bgs) for explosives, SVOCs, and metals analyses. Fifteen discrete samples were also collected from three depths for VOC analyses. Explosives compounds were not detected in any samples. Low levels of VOCs, SVOCs and metals were detected in some samples.

Twin Berms (Grids O15-16 and P15-16)

The twin berms are located to the immediate north of FFP-5 (Figure 2-4). A metal platform located at this area was apparently used as a firing point for artillery guns. The guns were fired downrange through the gap between the Twin Berms or at the berms from FFP-5.

During the initial sampling event conducted in 2000, a total of 13 samples were collected from four locations (SS101GA – SS101GD) (Figure 3-14). HMX was detected in seven samples from three locations (SS101GA, SS101GC and SS101GD) at concentrations ranging from 120 µg/Kg to 73,000 µg/Kg in the field duplicate sample collected from SS101GC (0 to 0.5 feet bgs).

A total of 24 samples were collected from seven additional sample locations in 2001 (SS101GE-SS101GK) (Figure 3-14). Explosives compounds were detected in eight samples from four of the seven locations, with maximum concentrations reported for HMX at SS101GF (990,000 µg/Kg), TNT at SS101GI (220 µg/Kg), 2A-DNT at SS101GF (200 µg/Kg), and 4A-DNT at SS101GF (210 µg/Kg).

Supplemental sampling was conducted in 2002 at existing locations SS101GF and SS101GI and five new locations, SS101GL – SS101GP (Figure 3-14). Maximum concentrations were detected for HMX at SS101GN (8,100 µg/Kg), RDX at SS101GI (120 µg/Kg), and low levels of 2-nitrotoluene (13 µg/Kg) and tetryl (17 µg/Kg), at SS101GM. Perchlorate was added as an analyte for these samples but was not detected in any of the samples collected. SVOCs, pesticides, PCBs, VOCs, and metals were detected in some samples. Based upon the presence of explosives compounds at locations SS101GM and SS101GN, seven additional samples were collected in 2004 from two locations: SS101GQ and SS101GR (Loc_IDs SS15171 and SS15172). Explosives compounds and perchlorate were not detected in these samples.

As a result of these investigations and soil sampling efforts, a RRA was conducted at the Twin Berm Area in 2004. A total of 651 cubic yards of soil contaminated with explosives compounds was excavated to a depth of 2.5 feet during the RRA (Figure 3-16). Excavated soils were thermally treated on-site. Two Target Control Pits (TCP) were encountered during the RRA excavation. The TCPs were excavated to depth and backfilled with clean soil. A total of five post-excavation soil samples were collected from three locations (SSJ2TB001 – SSJ2TB003). No explosives compounds or perchlorate were detected in any of the post-excavation samples. One inert M72 66mm LAW rocket and one inert M720 60mm mortar were discovered within this area during a surface clearance.

Range Road Burn Area (RRBA) (Grids N15-N17)

The RRBA is located in grids N15 to N17 at the southern end of the J-2 Range road where propellants were reportedly burned (Figure 2-4).

During the initial investigation in 2000, no MEC items were reported within the RRBA. A total of 12 samples were collected from four locations (SS101PA through SS101PD) in the area surrounding the RRBA (Figure 3-14) and submitted for a full suite of analyses, including VOCs, SVOCs, pesticides, PCBs, herbicides, TAL metals and explosives compounds. Composite samples were collected from three depths (0 to 0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1 feet bgs) at all locations. 2,4-Dinitrotoluene was detected in all three samples collected from SS101PD at concentrations ranging from 130 µg/Kg to 160 µg/Kg.

Based upon these results, additional grids were identified and sampled. A total of 17 samples were collected from five locations (SS101PE, SS101PH, SS101PI, SS101PP and SS101PQ) in August 2001 and July 2002 (Figure 3-14 and Figure 3-17). 2-Amino-4,6-dinitrotoluene and 4-amino-2,6-dinitrotoluene were detected in the surface soil sample (0 to 0.25 feet) collected from location SS101PI. Low levels of PCNs, VOCs, SVOCs and metals were detected in some samples.

During the RRA conducted at the RRBA in 2004, a total of 21 cubic yards of soil was removed to a depth of 0.75 feet, centered around sample location SS101PI and thermally treated on-site (Figure 3-16). The results for the post-excavation sample from location SSJ2RRBA001 were non-detect for explosives compounds and perchlorate.

Intrusive investigation of numerous geophysical anomalies within rows N15 to P17 resulted in the discovery of munitions debris and range residue debris in several areas (Figure 3-15). Polygon 17/18 contained a concrete pad, steel plates, and munitions debris. Polygons 19 through 21 contained only general refuse including concrete with steel pipe, angle iron, aluminum steps, steel pipe and galvanized pipe. Polygon 22 contained steel plates and polygons 23 through 25 contained numerous steel plates, concrete pad, concrete pipe, and railroad ties with spikes, as indicated in Table 1 of Appendix G. Location 16 contained munitions debris and other debris. No HE munitions items were found in these areas. The large geophysical features remaining in grid N15 and N16 represent range-related debris.

Supplemental geophysical surveys were also performed as quality control measures within selected grids (N15, O15, P15 and P16) to determine the effectiveness of previous munitions investigations and soil removal actions. No additional anomalies were selected for investigation based on the post-excavation geophysical record.

3.4.3.2 Grid Rows L18 to P21

Rows L18 to P21 include the south-central portion of Area 2 (Figure 2-4). The principal features located within these rows include Berm 3, a Mortar Position, and an MEC Disposal Area and Impact Area.

<u>Berm 3 (Grid N18)</u>

Berm 3, a 100-m berm, is the dominant surface feature in this portion of Area 2. This berm was presumably used as a backstop berm for FFP-3 and FFP-4.

In August 2000, a total of six samples were collected from two locations. SS101LA and SS101LB in the Berm 3 Area (Figure 3-14). Samples were also collected for VOC analysis from one location. HMX was detected in two samples from one location (SS101LA) at 140 µg/Kg (0.25 to 0.5 feet bgs) and 180 µg/Kg (0.5 to 1.0 feet bgs). Low levels of pesticides, herbicides, SVOCs, VOCs, and metals were detected in some samples. Munitions debris and metallic debris was also recovered from this area.

<u>Mortar Position (Grids N19-N20)</u>

The mortar position feature is located in grids N19 to N20 (Figure 2-4). As the feature title implies, this area was the former location of a mortar position. This area lies within the footprint of multiple increment sampling that occurred to delineate the extent of perchlorate and explosives contamination associated with the 30mm HEI projectile impact area.

During investigations in September 2000 and August 2001, a total of seven samples were collected from one location (SS101HA) (Figure 3-14). Explosives compounds were not detected in any of these soil samples. Low levels of PCNs, VOCs, SVOCs and metals were detected in some samples.

Munitions types found near the Mortar Position within these grids include 30mm HEI projectiles and 57mm small quantity energetic munitions containing small quantities of energetic material. These munitions are not likely associated with the use of this area as a mortar position.

MEC Disposal Area and Impact Area

Intrusive investigation of geophysical anomalies within rows L18 to P21 resulted in the discovery of numerous disposal pits. Munitions burial pits were identified in grids M19/20 and N19/20 (sub-polygons 14C, 15A, polygon 16, location 8 (M20-BLP-001), and location 28 (M20-BLP-002) (Figure 3-14).

Soil samples were collected in grids M19 and M20 (locations 101LC, 101LD, and 101LE) prior to intrusive investigation of geophysical anomalies in polygon 14/15. These samples were analyzed for VOCs, SVOCs, PCNs, metals, pesticides/PCBs, and herbicides. No explosives were detected in these samples.

Polygon 14 contained three sub-polygons 14A through 14C. Sub-polygon 14A contained five T330 30mm HEI projectiles that were BIP and determined to be HE. Sub-polygon 14C contained four inert 3.5-inch rockets, munitions debris and range-related debris. Sub-polygon 14B contained only munitions debris and range-related debris. Two subsurface soil samples were collected from the sub-polygon 14C excavation, including a composite sample from the excavated soil (J2.F.T14C.XC1.1.0) and a sample of native soil from the pit bottom (J2.F.T14C.XC1.2.0). Explosives and perchlorate were not detected in these samples. Approximately 120 cubic yards of soil was excavated from Polygon 14 and disposed of off-site.

Polygon 15 contained three sub-polygons, 15A through 15C. Sub-polygon 15A contained four T330 30mm HEI projectiles that were BIP and determined to be HE. In addition, four hundred eighty three inert 57mm projectiles, other munitions debris and range related debris were identified in this disposal pit. Sub-polygons 15B and 15C contained various debris and a steel plate. Two subsurface soil samples were collected from the sub-polygon 15A excavation, including a composite sample from the excavated soil (J2.F.T15A.XC1.1.0) and the pit bottom (J2.F.T15A.XC1.2.0). Explosives and perchlorate were not detected in these samples. Approximately 15 cubic yards of soil was excavated from Polygon 15 and disposed of off-site.

Soil samples were collected in grids N19 and N20 (locations 101HA, 101LF, and 101LG) prior to intrusive investigation of geophysical anomalies in polygon 16. These samples were analyzed for VOCs, SVOCs, PCNs, metals, pesticides/PCBs, and herbicides. No explosives were detected in these samples.

Polygon 16 alone contained five T330 30mm HEI projectiles that were BIP and determined to be HE. In addition, one 66mm rocket motor was found, BIP and determined to contain a small quantity of energetic material. Inert munitions, other munitions debris and range related debris were also discovered in this disposal pit. Two subsurface soil samples were collected from the polygon 16 excavation. Soil samples were collected from the excavated soil (J2.F.T16.XC1.1.0) and from the pit bottom (J2.F.T16.XC1.2.0). No explosives compounds or perchlorate were detected.

Location 8 was determined to be a MEC burial pit and was designated M20-BLP-001. Items found at this location included 69 T330 30mm HEI projectiles (14 of which were determined to have been fired), 286 inert 57mm projectiles and 180 expended 57mm cartridges. Various pieces of munitions debris and metallic debris were also found. The immediate area surrounding the finds was excavated in December of 2005 and a post-excavation sample was collected (LOCID: SSJ2M20007) and submitted for explosives, perchlorate and PCN analyses. Perchlorate was detected at 1,580 µg/Kg. PCNs were detected with a calculated TEQ of 3.8. The results for explosives were non-detect. A sample was collected from the soil stockpile and submitted for perchlorate, explosives, SVOC, RCRA 8 metals and PCN analyses. Perchlorate was detected at 97.5 µg/Kg. PCNs were detected with a calculated TEQ of 6.5. Explosive results were non-detect. Excavated soil was disposed of off-site.

Location 28 was determined to be a MEC burial pit and was designated M20-BLP-002. One thousand four hundred sixty seven T330 30mm HEI projectiles were discovered. In addition, 30mm fragmentation was found along with railroad ties and spikes. A discrete sample was collected from underneath one 30mm HEI projectile on January 19, 2006 after items were moved to the CDC and submitted for explosives and perchlorate analyses. Perchlorate was detected at 6,380 µg/Kg and RDX was detected at 1,200 µg/Kg. A post-excavation sample was collected after 12 cubic yards of soil was excavated from the burial pit and submitted for perchlorate and explosives analyses. Perchlorate was detected at 7.9 µg/Kg but explosives were not detected. A sample was collected from the soil stockpile and submitted for perchlorate, explosives, SVOC and TAL metals analyses. Perchlorate was detected at 267 µg/Kg. Some TAL metals and SVOCs were detected, including a few PAH compounds (benzo(a)anthracene, benzo(a)pyrene and benzo(b)fluoranthene). Explosives were not detected. Excavated soils were disposed of off-site.

All detected anomalies in grid O19 were investigated. Two former target control pits were discovered within grid O19 that contained railroad timbers and metal spikes. No munitions items or evidence of stained soil was found within the pits; soil samples were not collected. A 66mm LAW rocket warhead was discovered cracked-open with exposed HE. The soil at the base of this MEC item (ECC042205J202) was sampled and analyzed for explosives and found to contain detectable concentrations of 2-amino-4,6-dinitrotoluene, 4-amino-2,6-dinitrotoluene, and HMX. Five-point composite samples were collected from two locations in grid O19 (SSJ2SG003 and SSJ2SG004) and submitted for explosives compounds and perchlorate analyses. Samples were collected from three depths (0 to 0.25 feet, 0.25 to 0.50 feet, and 0.5 to 1 feet bgs) in an effort to delineate the extent of HMX, which had previously been detected in surface soil samples in this area. Results from sample location SSJ2SG004 collected at the 0.25 to 0.5 feet bgs interval indicated HMX at 10,000 µg/Kg. This HMX detection is addressed in the risk screening. Results from all other locations were non-detect. BIP samples were collected at SSJ2019002 and SSJ2019003. Location SSJ019003 was excavated. SSJ2019002 (ECC042205J202) was not and the HMX results (1,300 µg/Kg) remain in place to be addressed under the risk screen.

All detected anomalies in grid M21 were investigated. Predominant finds during investigations within grid M21 were single MEC items such as thirteen 30mm HEI projectiles, 57mm projectiles, 81mm mortars and 60mm mortars. One MEC item (Target 23), a 30mm HEI projectile, was cracked open with exposed high explosives. The soil at the base of this item was sampled (location SSJ2M21005) and submitted for explosives compounds and perchlorate analyses. RDX and perchlorate were detected in these samples at maximum concentrations of 300 µg/Kg and 8.2 µg/Kg, respectively. Thirteen 30mm HEI projectiles identified in grid M21 were BIP in addition to one 81mm and two 60mm mortars.

Additional disposal pits identified as polygons 8 and 10 were discovered in grids P20 and P21. Polygon 8 contained munitions debris scrap including gel-filled adapter boosters, expended fuzes, flash tubes, and other similar items. No MEC items were found in polygon 8. Polygon 10 contained MD scrap items and MEC items that were either inert or small-quantity energetic items, including 81mm mortars, 37mm projectiles, 105mm cartridge cases, etc. that are presented in Table 1 of Appendix G. Soil samples were collected from the excavated soil (J2.F.T8.001.1.0) and from the pit bottom (J2.F.T8.001.2.0) of polygon 8. No explosives were detected. Four surface soil samples were collected from one location (101KI) prior to intrusive investigation of polygon 9. Explosives were not detected in this sample. Polygon 9 was determined to be an impact area where 24 small excavations were completed to remove 32 inert 81mm mortars. Polygon 11 was an impact area where 60 small excavations were completed to remove 70 inert 81mm mortars.

A few of the anomalies investigated contained solitary or multiple (not buried) munitions. Anomalies in location 20 in grid M19 consisted of nine T330 30mm HEI projectiles, fragmentation and various pieces of scrap metal. Location 30 in grid M19 contained two inert M306 57mm projectiles in addition to debris related to a target control pit. Location 25 in grid M20 contained seven T330 30mm HEI projectiles, one 57mm inert projectile and fragmentation. A summary of all of the T330 30mm HEI projectiles, including those determined to be cracked/ leaking, found on J-2 Range is presented in Appendix G, Section 2.2.6 of this report.

Many of the locations investigated in rows L18 to P21 included inert munitions and miscellaneous munitions debris and range related debris. Tables 1 and 2 in Appendix G contain a detailed description of the locations and items found. These include Location 6 in grid M18 and Location 32 in grid M19. During clearance of a well pad in grid P19, one M374 81mm inert mortar with a live fuze was identified. In grid P18, one jet perforator was found (small quantity of energetic material). One M49 60mm mortar was found in grid N20 during the target control pit investigation, BIP and determined to be HE.

Supplemental geophysical surveys were performed as quality control measures within selected grids (M18, M19, M20, M21) to determine the effectiveness of previous munitions investigations and removals. No additional anomalies were selected for investigation due to the post-excavation survey, which indicated the effectiveness of the burial pit removal actions. The record suggested, however, that single MEC items may remain in grids that were not completely cleared of anomalies.

Supplemental geophysical surveys were also performed within grids N19, N20 and O19. J2N20 Area 2 contained seven T330 30mm HEI projectiles and various pieces of scrap and metallic debris. The record suggested that single MEC items may also remain within these grids.

The area around polygons 10 and 11 was resurveyed as a quality control method. J2P20 Area 1 contained one M751 PD fuze that was determined to be energetic and taken to the CDC. Other anomalies consisted of munitions debris and other debris.

In addition, a first-time geophysical survey was conducted along the southwestern perimeter of the range in grids L18 through L22 to identify the presence of any additional 30mm HEI projectiles. MEC items were discovered in the following locations: J2L19 Area 2 was determined to be a burial pit and was designated as L19-BLP-001. The soil sample (J2L19BLP001_PE) collected from under a cracked 30mm HEI projectile discovered in the pit had a perchlorate detection of 871 µg/Kg. The soil was excavated and disposed of off-site under the BIP management program. A post-excavation multiple increment sample collected at the base of the burial pit on 12/3/2007 had a perchlorate detection of 30 µg/Kg (Figure 3-17). One hundred three T330 30mm HEI projectiles, one inert 57mm cartridge case, one flare casing, and various pieces of MD and metallic debris were identified in this area. J2L19 Area 3 contained various pieces of scrap metal.

<u>30mm HEI Projectile Impact Area BIP-Related Sampling</u>

Multiple BIP events were conducted in rows L18 to P21, including at grids M19/M20. An important focus of these BIP events was to destroy the large number of 30mm projectiles found in rows L18 to P21. These items were discovered in grids M18, M19, M20, M21, N19 and N20.

From approximately 2000 to 2006, 326 BIP pre-, post-, supplemental and post-excavation samples were collected from 46 locations associated with BIP activities in Area 2 grids M19 and M20. BIP sample locations, sample identification, collection date, sample depths, sample types and laboratory analyses associated with this subarea of the range are listed in Table 3-9.

In 2006, approximately 300 cubic yards of contaminated soil associated with these BIPs was removed from this area under the BIP management program. A total of 63 post-, supplemental and post-excavation BIP-related samples for soils remaining in-place had detections of RDX and/or perchlorate. Eight samples collected from three locations had detected RDX results ranging from 91 µg/Kg to 2000 µg/Kg. The highest result at 2,000 µg/Kg was detected in a post excavation sample collected from location SSJ2M19005. A total of 55 supplemental and post excavation BIP samples collected from 11 locations had perchlorate detections ranging from 0.28 µg/Kg to 153 µg/Kg. The 30mm HEI projectile impact area is considered the primary source of the J-2 eastern plume. Additional sources also likely contributed to this plume. The excavated soil was disposed of off-site.

In 2009, extensive multiple increment sampling was conducted to provide a confirmatory assessment of the effectiveness of field investigations and RRA efforts. One hundred-point, multiple increment soil samples were collected from 0 to 0.25 feet bgs from multiple grids, including many in rows L18 to L21: M17, M18, M19, M20, M21, N18, N19, N20, N21, O19, and O20. Samples were analyzed for explosives compounds and perchlorate analyses. This sampling identified only low concentrations of perchlorate and no detections of RDX (Figure 3-15). Therefore, there was no additional soil excavation.

3.4.3.3 Grid Rows L22 to P26

Rows L22 to P26 are located in the north-central portion of Area 2 (Figure 2-4). Significant features in these rows include Berm 2 and Disposal Area 1.

<u>Berm 2 (Grids O24/O25)</u>

Berm 2, a 300-m berm, was used as a backstop berm for FFP-5. Berm 2 is located within grids O24 and O25 (Figure 2-4).

During initial investigations in September 2000, a total of 13 composite samples were collected from four locations (SS101KA, SS101KB, SS101KC, and SS101KD) (Figure 3-14; Table 3-9). Explosives compounds were detected in two samples collected from two depths at one location (SS101KA). The following explosives compounds were detected along with their maximum concentrations: TNT (320 µg/Kg), RDX (1200 µg/Kg) and HMX (8000 µg/Kg). These detections are consistent with the explosives filler, Octol, used in LAW rockets. The RDX detections may be the result of the impact of HE mortars or other munitions.

Monitoring well MW-137 was installed within this area. A total of 14 soil-boring samples were collected from the boring in October 2000. Five samples were submitted for explosives compounds analyses. RDX (220J µg/Kg) was detected in the sample collected from 0 to 0.5 feet bgs.

Soil was excavated from this area during the RRA in 2004 down to a depth of 1.5 feet (Figure 3-16). One post-excavation sample was collected (SSJ2B2001) and was non-detect for both explosives compounds and perchlorate. An approximate total of 173 cubic yards of soil were excavated and treated in the on-site thermal treatment unit.

Berm 2 was used as a backstop for the firing of the M72 66mm LAW rocket and 35mm LAW subcaliber rocket. High explosive and practice versions of the 66mm LAW rocket were also fired into Berm 2. A total of ten M72 66mm HE rockets were found during UXO clearance activities within the footprint of Berm 2 as shown in Figure 7 of Appendix G. Several inert 66mm LAW rockets and inert 35mm LAW subcaliber projectiles were also found at the foot of Berm 2. Small quantities of inert 66mm LAW rocket debris were also found in this area, as presented in Table 1 of Appendix G.

Disposal Area 1 (Grid N23)

Disposal Area 1 is located in grid N23 in the central portion of Area 2 on the north side of the Range Road (Figure 2-4). This area was reported to have been used for munitions disposal. Numerous inert M374 81mm mortars were found in this area. During well pad clearance for MW-120 in July 2000, 97 M374 81mm inert mortars were discovered. One inert M49 60mm mortar and one inert M107 155mm projectile were also found. Fourteen 30mm HEI projectiles identified as leaking were also found in July 2000 in this grid as presented in Table 5 of Appendix G.

Monitoring well MW-120 was advanced within this area in August and October 2000. A total of 12 soil-boring samples were collected from the boring. Five samples were submitted for laboratory analyses. Explosives compounds were not detected in any of the soil boring samples. Low levels of pesticides, herbicides, VOCs, SVOCs and metals were detected in some samples.

During investigations conducted from August 2000 through July 2002, a total of 75 soil samples were collected from 21 locations within the Disposal Area 1 (Figure 3-14). Composite samples were collected from three depths (0 to 0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1 feet bgs) at all locations. Samples collected for VOC analysis were discrete samples. Explosives compounds were detected in two soil samples collected from two locations (SS101NF and SS101NH). The following explosives compounds were detected, along with their maximum concentrations: HMX (1,200 µg/Kg), RDX (8,600 µg/Kg), and PETN (6,300 µg/Kg). The PETN detection remains in place and is evaluated in the risk screen (Section 6.0).

Several samples from this area were also submitted for polychlorinated naphthalene (PCN) analyses. PCNs were detected in several samples. Low levels of pesticides, herbicides, VOCs, SVOCs and metals were detected in some samples.

A total of 25 samples were collected from eight additional locations at Disposal Area 1 (SS101NU – SS101NZ, and SS101NPA and SS101NQA) in February and March 2004 (Figure 3-14). Explosives compounds were not detected in any of these soil samples. PCNs were detected in several samples. Low levels of pesticides, SVOCs and metals were also detected in some samples. The detections remaining in place are evaluated in the risk screen (Section 6.0).

During RRA activities in 2004-2005, soil was excavated from Disposal Area 1 (Figure 3-16). Prior to RRA excavation activities, surface clearance, vegetation cutting, and initial subsurface MEC clearance was performed in all work and support areas. Approximately 15 cubic yards of soil was removed from Disposal Area 1 during the RRA and thermally treated on-site, from a

30-foot by 60-foot area, to a depth of 0.75 feet. A post-excavation soil sample from location SSJ2DA1001 was non-detect for explosives compounds and perchlorate. One inert M374 81mm mortar with a live fuze was found during the surface clearance. One presumed HE, M374 81mm mortar was found during the soil excavation.

Four surface soil samples were collected from one location (101NL) prior to intrusive investigation of polygon 12 (Figure 3-15). Explosives were not detected in these samples. Polygon 12 consisted of several 6 by 6 by 1-inch steel plates. Six surface soil samples were collected from two locations (101IA and 101NM) prior to intrusive investigation of polygon 13. No explosives were detected in these samples. Polygon 13 was determined to be a disposal area containing unfired and inert 81mm mortars.

Thirteen surface soil samples were collected at four locations (101KE, 101KF, 101KG, and 101KH) in polygon 6 and 7 prior to intrusive investigation. These samples were analyzed for VOCs, SVOCs, PCNs, metals, pesticides/PCBs, and herbicides. No explosives were detected in these samples.

Intrusive investigation of additional geophysical anomalies resulted in the discovery of several disposal pits within rows L22 to P26. Polygon 6 contained four sub-polygons that were designated 6A through 6D. All of these were determined to be munitions burials. Sub-polygon 6A contained a 66mm rocket motor with a small quantity of energetic material; a 40mm MK2, presumed HE unknown fuze and a small quantity of energetic material; one M1 105mm projectile HE; 27mm subcaliber with a small quantity of energetic material; 35mm subcaliber with a small quantity of energetic material; three M720 60mm mortars with a small quantity of energetic material; ball ammunition with a small quantity of energetic material; and four M374 81mm mortars with a small quantity of energetic material. Thirteen M51 fuzes were found with a small quantity of energetic material in sub-polygon 6A. Other inert munitions that were found are listed in Table 1 of Appendix G. Sub-polygon 6B contained metallic debris. Sub-polygon 6C contained mostly inert munitions items including twenty-nine 105mm cartridge cases with live primers. Sub-polygon 6D contained mostly inert munitions items; 11 M374 81mm adapter boosters, two M72 66mm LAW rockets inert with live motors, one 3.5-inch unfired rocket motor, and 95 booster cups that were taken to the CDC. Polygon 7 was an impact area where 138 small excavations were completed to remove 208 inert 81mm mortars.

A few of the anomalies investigated contained solitary or multiple (non-burial) munitions. Locations 15 and 18 in grid N23 were determined to be munitions that were staged on pallets. These munitions were subsequently removed. Many of the locations investigated included inert munitions and miscellaneous munitions debris and range related debris. Tables 1 and 2 in Appendix G contain a detailed description of the locations and items found. These areas include Location 36 in grid N23; Location 33 in grid M24 and Location 34 in grid O24. Additional items (three M72 66mm HE LAW rockets) were found during a well pad clearance for MW-137 in grid O24. Several large anomalies in grids O22, O23, and O24 along with a few other isolated anomalies were identified. A target control pit, anomaly ID023010, was found within grid O23. No munitions items or evidence of stained soil was found within the pit and therefore, no soil samples were collected during the investigation of these areas. None of the anomalies investigated were indicative of disposal activities.

One MK1 30mm HEI projectile, one M72 66mm LAW rocket, and two T330 30mm HEI projectiles were found in grid O24. These were BIP and determined to be HE. In addition, one impulse cartridge, three M201 fuzes, and one rocket motor were found in grid O24 and taken to the CDC. One M557 fuze was found in grid O25 and taken to the CDC for disposal. North of Area 2 outside the grid area, one T330 30mm HEI projectile and two M51 PD fuzes were found.

Supplemental geophysical surveys were conducted in select grids as quality control measures to determine the effectiveness of previous munitions investigations and removals. Only munitions debris or other debris was identified in M24. The survey conducted within grids N22 and N23, the location of Disposal Area 1, resulted in the investigation of certain anomalies. J2N22 Area 1, J2N22 Area 2, and J2N23 Area 1 revealed munitions debris and other range related debris. Location 21 in grid N24 consisted of many munitions types including one T330 30mm projectile identified as leaking that was taken to the CDC and determined to be HE. Inert munitions (e.g., M60 igniters, tail booms, M54 rocket motors, M18 warhead, flashtube, fuzes, and fragmentation), and debris items (e.g., wire, glass jars, spikes and tent pegs) also were discovered in Location 21. Anomalies investigated within grids P22 through P24 in the area of polygons 6 and 7 revealed only munitions debris and other debris. Munitions debris was identified in grid O25 behind Berm 2.

3.4.3.4 Grid Rows L27 to O29

Rows L27 to O29 are located at the northwestern end of Area 2 (Figure 2-4). The principal feature located within these rows is the Brick-lined Pit 1.

<u>Brick-lined Pit 1 (Grid M28)</u>

Brick-lined Pit 1 is located at the northern end of Area 2 in the J-2 Range and is associated with the former transition range. The pit was used for the historic disposal of munitions and other debris and was investigated and removed in conjunction with Brick-lined Pit 2 (Area 1) in 1999. As described in the original investigation report of the brick-lined pits (Ogden 1999), only small caliber munitions and spent (inert) casings and no HE/HEI rounds were found. Munitions excavated from Brick-lined Pit 1 included 1000 pounds of various scrap munitions, including 0.50 cal, 7.62mm, 0.30 cal, M1 clips, M20 smoke grenade canisters, and LAW rocket motors.

A total of three composite samples were collected from this location (location SSBP01) (Figure 3-14). Explosives compounds, pesticides, PCBs, or herbicides were not detected in any of the samples. Lead and molybdenum were the only metals detected. Based on the general absence of significant contaminants, no additional delineation sampling was conducted. During a surface sweep of grid M28 (where Brick-lined Pit 1 was located) in June 2000, three inert 57mm projectiles containing small quantities of energetic material were identified.

In August and October 2000, monitoring well MW-117 was advanced through Brick-lined Pit 1 and a total of 12 soil samples were collected from the boring. Explosives compounds were not detected in any of the soil boring samples. Low levels of herbicides, VOCs, SVOCs and metals were detected in some samples.

Only one other MEC item was found in these rows. One M18 66mm LAW rocket was found in grid N28 and was sent to the CDC.

3.4.3.5 Grids Outside of Area 2

Four grids outside of the J-2 Range Area 2 boundary (i.e., L29, K30, K31, and K32) were investigated during a non-intrusive reconnaissance using hand-held magnetometers in January 2007 (ECC 2007). Subsurface anomalies were classified based on the spatial extent of the signal response of the magnetometer. Two large Type F (i.e., greater than 13 feet in spatial extent) anomalies were identified and are shown on Figures 3-14 and 3-17. The large Type F anomaly in grid L29 bordering K29 was determined to be a group of three adjacent target control pits. Only two pieces of RRD and no MEC or MD was found on the surface within the boundaries of the anomaly and it was not investigated further. The second Type F anomaly, bordering grid M29, was investigated in 2007 and designated J2L29 Area 1. As shown in Table 1 of Appendix G, only scrap and sheet metal was found in this area. No other Type F anomalies were found in these grids.

3.4.3.6 Area 2 BIP-Related Sampling

A total of 1,010 BIP pre-, post-, supplemental and post-excavation samples were collected from 159 locations associated with BIP activities in Area 2. Three hundred four samples were pre- and post-BIP samples. A total of 526 supplemental samples were collected from 76 locations and 180 post-excavation samples were collected from 48 locations. Results of all BIP sampling are presented in the associated annual BIP report. BIP sample locations, sample identification, collection date, sample depths, sample types and laboratory analyses associated with this subarea of the range are listed in Table 3-9.

A total of 148 supplemental and post-excavation BIP-related samples from soils remaining in-place have detections of RDX or perchlorate. Twenty-four samples collected from 16 locations have RDX results ranging from 14 µg/Kg to 5600 µg/Kg. The highest result at 5,600 µg/Kg was detected in a post-excavation sample collected from location OG071900-03_21 in grid N23. BIP locations having RDX and/or perchlorate exceeding MCP S-1/GW-1 Standards will be excavated under the BIP protocols. This detection is addressed in the risk screen. A total of 120 supplemental and post-excavation BIP samples collected from 24 locations have perchlorate detections ranging from 0.28 µg/Kg to 153 µg/Kg. The post-excavation samples collected from location SSJ2M19005 had detected results of both RDX and perchlorate; RDX was detected at 1,800 and 2,000 µg/Kg in two samples. Perchlorate was detected in five samples ranging from 61.4 to 153 µg/Kg.

3.4.3.7 Area 2 Source Characterization Conclusions

The conceptual site model of this portion of the range was developed from range characteristics, range records, review of aerial photographs, and intrusive investigation finds. The development of the conceptual site model is presented in Appendix G. The available information suggests that this area was used for firing positions, as an impact area during the testing of 66mm LAW rockets and 30mm HEI projectiles containing HE, and for inert 57mm projectiles and various mortars, for disposal of MEC, and as a general disposal area.

<u>Grid Rows N15 to P17</u>

This area of the range appears to have been primarily used as firing positions, for the burning of propellant, and as an impact area for HE items. Contaminated soils were removed from areas around FFP3, FFP4, twin berms, and the RRBA during the 2004 RRA. Only one MEC item, a broken open 30mm HEI projectile found in grid O17, was observed at these locations. Intrusive investigations of polygon areas 17 through 25 revealed the presence of concrete pads, steel plates, scrap metal and piping and munitions debris at certain locations. No HE items were found in these areas. The remaining uninvestigated anomalies are not expected to be disposal areas based upon the nature of the remaining geophysical response. Individual items may remain.

Grid Rows L18 to P21

This area of the range appears to have been primarily used as an impact area for both HE and inert munitions, and as a MEC Disposal Area. Intrusive investigations in rows L18 to P21 revealed the presence of numerous burial pits. Munitions burial pits were identified in grids L19, M19/20 and N19/20. 30mm HEI projectiles and inert 57mm projectiles were the primary munitions found although some other types of munitions were identified at certain locations. Significant quantities of T330 30mm HEI projectiles were found in grids L19, M19 and M20 and individual projectiles were found at multiple additional locations within polygons 14, 15, 16 and locations 8 and 28. As can be seen in Table 2 of Appendix G, a total of 1,908 30mm HEI projectiles or parts were discovered in grids M19 and M20. Of these, a total of 1,467 projectiles were found in disposal pit M20-BLP-002 and were destroyed in the CDC. An additional 69 projectiles were found in M20-BLP-001 and were destroyed by BIP. In grid M20, a total of 104 fuzes and 24 items identified as “explosive compound” were destroyed in the CDC. The remaining 244 individually (1-7 found at a location) located 30mm HEI projectiles identified in this area outside of the identified burial pits (128 in grid M19, of which 21 were identified as leaking, and 116 in grid M20, seven of which were identified as leaking) were destroyed either in the CDC or during BIP events conducted from 2000 to 2006. Subsequently, contaminated soil was excavated from these BIP locations in 2006. Remaining detections will be excavated under the BIP management program. In 2009, confirmatory multiple increment sampling was performed at multiple locations in Area 2, including many grids in rows L18 through P21. Multiple increment soil sampling results indicated the presence of only low levels of perchlorate and no RDX. As a result no further excavations were implemented.

Small quantity energetic items were identified in polygons 10 and 16 and in grid P20. Other areas where congregations of inert items were identified were polygons 8, 9, 11 and 14B and grids M21 and O19.

In February 2013, three anomalies in each of grids N18, O18, and P18 (for a total of nine additional anomalies) were investigated in this area. Two anomalies were designated as “No Find” (i.e., no metallic items were found at that location). The other seven anomalies contained non-munitions surface debris such as barbed wire, a timber gate abutment, steel pipe, a concrete block, timber with nails, and a steel fence post. No MEC items were found.

Grid Rows L22 to P26

The primary features in this area were burial pits and disposal areas, and a target backstop berm. In rows L22 to P26 certain explosives (TNT, RDX and HMX) were detected in three samples from Berm 2. Explosives including RDX, HMX and PETN were also detected in some soil samples collected from Disposal Area 1. RRA soil excavations were conducted at both Berm 2 and Disposal Area 1 during 2004-2005 with approximately 173 cubic yards of soil removed from the former location and 15 cubic yards removed from the latter. Intrusive investigations in rows L22 to P26 revealed the presence of several disposals pits that were determined to be munitions burial sites. Sub-polygons 6A through 6D were found to contain a variety of munitions and munitions debris, including mortars, fuzes, cartridge cases and booster cups. In polygon 7, multiple excavations were conducted to remove 208 inert 81mm mortars.

In February 2013, 16 additional anomalies were surveyed and are located in grids M22 (one anomaly), O22 (three anomalies), O23 (four anomalies), O24 (two anomalies), and O26 (six anomalies). The anomaly location in grid M22 contained surface debris consisting of large spikes and railroad ties. All of the anomalies in grids O22 and O24 had “No Finds”. Grid O23 contained one anomaly designated “No Find”, one anomaly with one piece of unidentified frag, and one anomaly location whose signal was too deep to identify and requires further investigation to identify. Grid O26 contained two locations with surface debris (i.e., a railroad tie and a 4 foot by 4 foot metal grating) and four locations with munitions debris (i.e., three locations with unidentified frag and one M51 series fuze, expended). No MEC was found in these grids during this investigation.

Grid Rows L27 to O29

In rows L27 to O29, no explosives compounds were detected in samples collected from Brick-lined Pit 1. Munitions excavated from this location included 1,000 pounds of scrap munitions including 0.50 cal, 7.62mm, 0.30 cal, M1 clips, M20 smoke grenade canisters, and LAW rocket motors. A total of 17 MEC items were found scattered throughout these rows as presented in Table 2 of Appendix G. A total of five MEC items (one M18 66mm LAW HE rocket, one T330 30mm HEI projectile, one M720 60mm inert mortar, one 57mm inert projectile, and small quantity of pyrotechnic residue) were destroyed in the CDC. Two items (one M433 HEDP 40mm HE projectile and one M374 81mm HE mortar) were destroyed during BIP events. The remaining 7 items, all designated inert, were moved to the safe holding area and eventually destroyed.

In February 2013, a total of 23 additional anomalies were surveyed in this area. The anomalies surveyed in grid O27 (10 anomalies) were all either “No Finds” (two anomalies), surface debris (i.e., one anomaly with 40 feet of barbed wire) or munitions debris (i.e., unidentified frag at four anomaly locations, two M29 3.5-inch rocket motors (expended) at two separate locations, and one location with a M29 3.5-inch rocket nose cone). The 13 anomalies in grid O28 yielded two anomaly locations with “No Find”, two locations with railroad ties (i.e., surface debris), and nine locations with munitions debris, including six anomaly locations with frag, and three locations with M301 81mm illumination mortar pieces (i.e., 2 bodies and one tail). No MEC items were found in either grid.

A quality control geophysical survey along with an intrusive investigation of residual anomalies has been conducted over a large portion of Area 2. It is unlikely that any subsurface burials remain. Spatially large geophysical anomalies are reflective of surface debris (Figure 3-17). Remaining spatially small geophysical anomalies are scattered and are likely to be residual munitions, munitions debris and other debris. Individual MEC items, both high explosive versions and inert with live fuzes may remain. Individual MEC items are likely to include 30mm HEI projectiles. Individual projectiles have been identified throughout Area 2. Significant quantities were identified in the southwestern portion of Area 2, centered on grids M19/M20. Many of the projectiles within grids M19 and M20 were determined to be cracked and/or leaking (see Table 5 of Appendix G). In addition to these fired projectiles found at depths ranging from 0 to greater than 12 inches bgs, two munitions burial pits containing these projectiles were also identified within grid M20. These features are considered the primary contributors to the J-2 eastern plume.

3.4.4 Area 3 – Disposal Area (Rows 30 to 35)

Area 3 is located in the central portion of the J-2 Range (Figure 2-4) and encompasses Rows 30 to 35. The primary activity that was conducted in this area was burning and burial of MEC. The following specific site features are or were formerly located within the Disposal Area:

- Berm 5
- Disposal Area 2

- Polygon 1
- Brick-Lined Pit 2
- Anomaly West of Polygon 1
- Anomaly North of Polygon 2
- BIP Crater - J2.A.T1A.021 & 022

In addition, the following significant features were identified as a result of intrusive investigation of geophysical anomalies:

- Burn/burial pits: Approximately 19 individual burn and burial pits (sub-polygons) collectively comprised investigation areas identified as polygons 1 and 2. Polygons 1 and 2 and the surrounding area are known as Disposal Area 2.

Soil sampling was generally focused on the features listed above. A description of each of these features was previously presented in Section 2.2. The J-2 Range Rows 30 to 35 soil data set represents site investigations conducted from July 1997 through September 2008. A total of 790 soil samples were collected from 172 locations within this portion of the range. In most cases, samples were collected from multiple depths at each location, resulting in a larger number of samples than actual sample locations. Additional details about soil samples collected around each feature within Area 3 are discussed below and presented in Table 3-12. Table 3-13 summarizes analytical detections in soil that has already been excavated during various intrusive investigations, removal actions, or in conjunction with BIP activities. Table 3-14 summarizes analytical detections for all soil samples that represent current in-situ site conditions. Soil sample locations as well as locations and descriptions of MEC items identified in the field are depicted on Figure 3-18. Figure 3-19 shows areas excavated during RRA activities, and Figure 3-20 depicts current site conditions, and includes chemical results boxes for samples with explosives compounds or perchlorate detections. The complete analytical data set for all soil results collected through 2008 is included in Appendix F.

Munitions items were categorized based on their explosive characteristics. The categories developed include high explosive (HE) high explosive incendiary (HEI), possible HE, Propellant/Energetic, Small Quantity Energetic, and Inert. Munitions items that were classified as HE were positively identified as HE (e.g., lot number or post-BIP results indicative of high explosives). The HEI designation is a special designation relating to the 30mm projectiles found on the Base. Items that were classified as “possible HE” were munitions items that were presumed to contain HE on initial discovery and were either disposed in the CDC or BIP, where the actual presence of the HE was not conclusively established or was not recorded. Items classified as Propellant/Energetic include raw propellant, chunk explosives or bulk explosives. Items classified as Small Quantity Energetic were MEC items that contained small amounts of energetic materials in one or more components (fuzes, detonators spotting charges). Items classified as inert were munitions items that were presumed to be HE on initial discovery but post-BIP or CDC results indicated that the item was inert.

3.4.4.1 Grid Rows L30 to P31

The southeastern end of Area 3 abuts Area 2. The principal feature in this portion of Area 3 is Berm 5. The southeastern tip of Disposal Area 2 also extends into grid N30. Disposal Area 2 is discussed in Section 3.4.4.2.

Prior to the initial ground-based geophysical survey in 2000, a surface clearance was conducted over the footprint of the J-2 Range including Area 3. The following items were found in grids L30 to P31. Five M63/M83 37mm HE projectiles with base detonating fuzes and one 3.5 inch rocket motor and residual M7 propellant were identified and disposed of in the CDC. In grid M30, six M63 37mm HE projectiles were taken to the SHA and eventually destroyed, and two smoke canisters determined to contain energetic were disposed of in the CDC.

Berm 5

Berm 5 is located within grid M30 (Figure 3-18). This berm was identified in interviews of former range personnel as a 500- meter or 500- yard Berm. Based on its location on the southwest side of the range road, it was likely used as a backstop for firing points at the southwest part of the contractor area. A total of 20 composite samples were collected from six sample locations prior to excavation activities (SS101MA, SS101MB, SS101MC, SS101MD, SSJ2B5001, and SSJ2B5002) (Figure 3-18). Perchlorate was detected in samples collected from location SSJ2B5001 (3.6-3.8 µg/Kg) and SSJ2B5002 (7.6 µg/Kg) (Table 3-7). A total of approximately 497 cubic yards of soil were excavated from Berm 5 as part of soil rapid response action (RRA) and removed from this area in 2004 and treated at the on-site thermal treatment unit. Post-excavation confirmation samples were collected after each one-foot lift was removed. Final confirmation samples were non-detect for perchlorate. 2,4,6-Trinitrotoluene was detected at 510 µg/Kg in the 3 to 3.5 feet bgs confirmatory sample collected from location SSJ2B5001. This detection remains in place and is evaluated in the risk screen (Section 6.0).

MEC items were discovered in grid M30 during investigations and in support of the soil RRA at Berm 5. MEC items recovered and BIP include one M433 40mm HE projectile, three T330 30mm HEI projectiles and one M720 60mm mortar containing a small quantity of energetic material. One inert M374 81mm mortar with a live fuze was also found in grid M30. Munitions debris and other metallic debris were also encountered at Berm 5.

RDX was detected at 620 µg/Kg in a post-BIP sample collected from location J2A200595 located in Grid L30. Supplemental samples were collected and were all non-detect. A 5-foot by 5-foot area was excavated to 1-foot depth; post-excavation samples were collected and were all non-detect. The area was backfilled with clean soil. The excavated soil was disposed of off-site.

- MEC items were also found at the following locations in grid rows L30 to P31: One 40mm HE projectile was discovered in support of the sub-polygon 3D investigation in grid L31. Fifty-six empty 105mm cartridge casings with live primers (small quantity energetics) were discovered in support of investigation of polygon 4 in grid O30, and one M49 60mm HE mortar was discovered in support of the investigation at Location 5 in grid L31.

3.4.4.2 Grid Rows L32 to P35

Most of the principal features of Area 3 are encompassed by rows L32 to P35, including most of Disposal Area 2, Brick Lined Pit 2, the anomaly west of polygon 1, the anomaly north of polygon 2 and BIP crater J2.A.T1A.021 and 022. MSP polygons and pit discrimination analysis polygons were also identified in this area.

Prior to the initial ground-based geophysical survey in 2000, a surface clearance was conducted over the footprint of the J-2 Range Area 3. The following items were found within grid rows L32 to P35:

- In grid M32, one unfired M407 40mm grenade (small quantity energetic) was found.
- In grid N33, one pyrotechnic item (small quantity energetic) was found.

- In grid O33, one M43 81mm HE mortar was found.
- In grid N31, one 57mm projectile (small quantity energetic) and one 30mm HEI projectile were found.
- In grid O31, one 12-pound HE cannonball was found.
- In grid O30, one M23 rifle smoke grenade (small quantity energetic) was found.
- In grid L34, one unfuzed 57mm HE projectile was found.
- In grid N33, one M433 40mm (presumed HE) projectile was found.

Brick-lined Pit 2

Brick-lined Pit 2 is located in grid L33, in the southwestern corner of Area 3. Brick-lined Pit 2 was historically used for the disposal of munitions and other debris, and was investigated and removed, along with the contents, in 1999. As described in the original investigation report of the brick-lined pits (Ogden 1999), only small caliber munitions and spent (inert) casings and no HE/HEI rounds were found. Munitions excavated from this location included one 40mm flare cartridge (empty), two 3.5-inch rocket motors (expended), and one 3.5-inch rocket practice head. Since that original investigation, no munitions items have been found in this grid. Two composite samples were collected, one from the sidewall, and one from the bottom (SSBP02). A composite sample was also collected of the soil removed from the excavation. Explosives compounds were not detected in any of the samples.

Monitoring well MW-119 was advanced through Brick-lined Pit 2, and a total of 13 soil samples were collected from the boring in August 2000. Explosives compounds were not detected in any of the soil boring samples. Low levels of SVOCs, VOCs and select metals were detected in some samples. Detected results remaining in place are evaluated in the risk screen (Section 6.0). No MEC items were reported within the Brick-lined Pit 2.

Disposal Area 2

Disposal Area 2 is the predominant feature located in Area 3 of the J-2 Range (Figure 3-18) and extends from grid N30 to grid O35. Disposal Area 2 was reportedly used for demolition and disposal of small firearms, dynamite, and fireworks. Numerous MEC items have been found at this location. Items found in this location and identified as HE include (but are not limited to): bulk propellant, 20mm projectiles, 40mm grenades, 60mm mortars, 105mm projectiles, 2.36-inch rockets, 37mm projectiles, 30mm projectiles, and 66mm rockets. Small quantity energetic items found in Disposal Area 2 include but are not limited to unfired 20mm projectiles and 40mm grenades, smoke and/or illumination signals, shaped charges, cartridge cases, flares, explosive bolts, rocket motors, small arms ammunition, igniters, propellant (including M7 propellant pieces, 2.75-inch rocket propellant, and unidentified propellant), and various fuzes.

Disposal Area 2 primarily consists of areas identified as polygon 1 and polygon 2. These polygons are themselves comprised of numerous sub-polygons based on discrete geophysical anomalies. Although polygons 1 and 2 were defined as disposal areas, burn pits were discovered within these sub-polygon disposal areas. Soil samples were collected from excavated soil and excavation bottoms in these polygons and sub-polygons, and at burn pit locations at or near several of the sub-polygons. MEC items were also found outside the limits of polygons 1 and 2 during clearance activities conducted in support of the soil RRA in this area. Table 2 of the MSA Report provides a detailed list of items found.

A total of 103 samples were collected from 44 sample locations within Disposal Area 2 from August 2000 through May 2004. Composite samples were collected from three depths (0 to

0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1 feet bgs) at all locations. Samples collected for VOC analysis were discrete samples. Explosives compounds were detected in 44 soil samples from 23 locations. The following explosive compounds were detected, along with their maximum concentrations: HMX (4,700 µg/Kg), RDX (230J µg/Kg), TNT (57,000 µg/Kg), 2,4-DNT (44,000 µg/Kg), 2,6-DNT (2,200 µg/Kg), 2A-DNT (5,200 µg/Kg), 4A-DNT (4,100 µg/Kg), nitroglycerin (10,000 µg/Kg) and tetryl (3,300 µg/Kg).

Twelve soil samples were also collected from the boring at MW-130, located in the center of Disposal Area 2 (grid N33, Figure 3-18). Explosives compounds were not detected in any soil boring samples by method SW8330. Only a trace level of 2,4-DNT was detected (50 µg/Kg) by method SW8270 in the 0 to 0.5 feet bgs sample collected from MW-130.

Disposal Area 2 has been identified as the primary source of the J-2 Range northern groundwater plume, and was targeted for excavation during the soil RRA conducted from 2004 through 2006. During that time a total of approximately 3786 cubic yards of soil were excavated from Disposal Area 2 and treated in the on-site thermal treatment unit. The RRA activities focused on areas within Disposal Area 2 with the highest levels of TNT, nitroglycerin, RDX and HMX. A total of 33 post-excavation composite soil samples were collected from 21 locations during the RRA excavation activities. Based on post excavation sampling results, subsequent one-foot lifts were excavated from portions of Disposal Area 2 due to detections of explosives compounds or perchlorate at sample locations SSJ2P2004, SSJ2P2005, SSJ2P2006, SSJ2P2007, SSJ2P2012, SSJ2P2015, and SSJ2P2016. Due to detections of explosives compounds at the base of excavations at SSJ2P2005 and SSJ2P2016, an additional 1-foot lift of soil was removed from these two locations. Ultimately, confirmatory samples indicated no detectable concentrations of explosives compounds or perchlorate remained.

MSP Polygon 2

MSP polygon 2 was divided into 24 sub-polygons (2A through 2W) based on discrete geophysical anomalies that were each found to correspond to a burial pit (Figure 3-18). MEC items were discovered within the sub-polygons as well as munitions debris and other debris. Items include fuzes, cartridge actuated devices, live primers, 20mm projectiles, 3.5-inch rockets, small arms and other energetic items. Fourteen of the 24 sub-polygons in polygon 2 (2B, 2C, 2D, 2E, 2G, 2H, 2J, 2K, 2M, 2P, 2R, 2S, 2T, 2V) were found to contain burn pits and two sub-polygons (2I, 2U) contained burial pits. The remaining 8 sub-polygons (2A, 2F, 2L, 2N, 2O, 2Q, 2W, 2X) were found to contain neither burn pits nor burial pits. UXO scrap was found at almost all of the locations. A complete description of the items found in each sub-polygon can be found in the J-2 Range polygon report (Tetra Tech 2003a). Table 1 of Appendix G contains a detailed list of all MEC items found. Table 1 of the J-2 Range MSA Report provides a detailed list of MEC items discovered.

During MEC clearance associated with the RRA in 2004, excavation material from five grids in Disposal Area 2 exhibited evidence of debris from MEC burn activities. Two burn pits were encountered in grid N32, one burn pit in grid N33, and two burn pits in grid O34. Post excavation samples collected from these burn pits were non-detect for explosives compounds and perchlorate (Locations SSN32001, SSN32002, SS10629-A, SS10585-A, SSJ2T2K, SSJ2T2J, SSJ2T2E, SSJ2T2G, SSJ2O34002, SSJ2O34BNP, SS10423-A, SS10400-A and SS10512-A). Burn pit investigations are discussed in detail in the *Final J-2 Range Rapid Response Action Completion of Work Report* (ECC 2007).

Sub-polygons excavated and backfilled during the MSP, where post-excavation soil samples showed detections of target compounds, were excavated and sampled during 2006. Sub-polygons 2E (location SSJ2T2E), 2G (SSJ2T2G), 2J (SSJ2T2J), 2K (SSJ2T2K), 2T (SSJ2T2T), and 2U (SSJ2T2U) were excavated, and five-point composite samples were collected from the base of the excavations. All post-excavation sample results were non-detect for explosives compounds and/or perchlorate, with one exception. Perchlorate was detected in the post-excavation sample collected from location SSJ2T2J at 0.37 µg/Kg. An additional 120 cubic yards of soil was excavated and disposed off-site at an approved facility.

MSP Polygon 1

MSP polygon 1 is located in grids M32 and M33. MSP polygon 1 was divided into three sub-polygons (1A, 1B, and 1C), each of which was a burn pit. A total of 21 samples were collected from six sample locations within the polygon 1 from August 2001 through December 2002. Composite samples were collected from three depths (0 to 0.25 feet, 0.25 to 0.5 feet, and 0.5 to 1 feet bgs) at all locations. Samples collected for VOC analysis were discrete samples. Explosives compounds or perchlorate were detected in 11 soil samples from six locations. The following explosives compounds were detected, along with their maximum concentrations: RDX (17J µg/Kg), 2,4-DNT (500,000 µg/Kg), 2,6-DNT (18,000 µg/Kg), nitroglycerin (13,000 µg/Kg) and 4-NT (44J). The highest detections of explosives compounds were in the sample collected from 0 to 0.25 feet bgs at location SS101OT. Perchlorate was detected in samples collected from location SS15192-A; with the highest detection (4.0J µg/Kg) in the sample collected from 0.25 to 0.5 feet bgs.

MEC items recovered from sub-polygon 1A consisted of thirty M935 point detonating (PD) fuzes; 259 unfired, presumed HE M56A1 20mm HEI projectiles: 112, live 20mm cartridge cases, two hundred twenty-eight 40mm cartridge cases with live primers, as well as other small quantity energetic items. Thirty-eight M383/M533 40mm practice grenades with PD fuzes and thirteen M407/M551 40mm practice grenades were also identified. Table 1 of Appendix G contains a detailed list of all MEC items found.

MEC items recovered from sub-polygons 1B and 1C consisted of small quantity energetic items similar to those discovered in sub-polygon 1A. Items include fuzes, cartridge actuated devices, live primers, 20mm projectiles and other energetic items. Table 1 of Appendix G contains a detailed list of all MEC items found.

Three composite post-excavation samples were collected from three locations within polygon 1 in 2004 during RRA activities (SSJ2P1001, SSJ2P1002 and SSJ2P1003). Explosives compounds and perchlorate were not detected in these samples. A total of 435 cubic yards of soil were excavated from polygon 1 during the RRA for on-site thermal treatment.

Sub-polygons where post excavation soil samples showed detections of target compounds were excavated in 2006. These areas included sub-polygons 1A (sample location SSJ2T1A, RDX at 6,600 µg/Kg), and 1C (SSJ2T1C, RDX at 2,800 µg/Kg) within the polygon 1 boundary. Five-point composite soil samples collected from the bottoms of the final excavations were non-detect for explosives and perchlorate.

Anomaly West of Polygon 1

Two pre-excavation composite samples were collected from locations SS101EAA and SS101FAA in 2004 within the boundaries of an anomaly located west of polygon 1 (grids L33 and L34). Samples were collected from a depth interval 0 to 1.5 feet bgs in order to determine the required depth of excavation in advance; discrete samples were collected for VOC analysis.

One unfuzed 57mm HE projectile was found during the surface sweep conducted prior to the geophysical survey. One M50/A2/A3 60mm inert mortar (with live fuze) was discovered during the investigation and support of the soil RRA in this area. Soil was excavated from this location during the RRA down to a depth of 1.5 feet. Two post-excavation samples were collected (SSJ2SWP1001 and SSJ2SWP1002) and were non-detect for explosives compounds and perchlorate. A total of approximately 234 cubic yards of soil were excavated and treated in the on-site thermal treatment unit.

Anomaly North of Polygon 2

Two pre-excavation 5-point composite samples were collected from locations SS101Z and SS101AAA in 2004 from an anomaly located north of polygon 2 in grid P34. Several MEC items were discovered during the investigation and in support of the soil RRA. These MEC items consisted of one M433 40mm HE grenade, two M56A3/M56A4 HE projectiles, and four small quantity energetic items as detailed in Table 2 of the J-2 MSA Report. Soil was excavated from this location during the RRA down to a depth of 1.5 feet. Two post-excavation samples were collected (SSNEP2001 and SSNEP2002). Results from post-excavation sample SSJ2NEP2002 were non-detect for perchlorate and explosive compounds. However, an additional 1-foot lift of soil was excavated from this area, due to the detection of 2A-DNT and 4A-DNT in the post-excavation sample collected from SSJ2NEP2001. The confirmatory sample collected after the additional excavation was non-detect for explosives. A total of approximately 249 cubic yards of soil were excavated and thermally treated on-site.

BIP Crater – J2.A.TIA.021 & 022

During the investigation of polygon 1, located in grid M32, two separate detonations of 40mm projectiles were conducted in 2002. Pre- and post-BIP samples were collected from locations SS10329 and SS10330. Soil was excavated from this area during the RRA to a depth of 0.75 feet. One post-excavation sample (SSJ2ATA1A001) and a field duplicate sample were collected. Results were non-detect for explosives compounds and perchlorate. A total of 14 cubic yards of soil were excavated from MSP polygon 1 for on-site thermal treatment.

Supplemental geophysical surveys were conducted in select grids as quality control measures to determine the effectiveness of previous munitions investigations and removals. The following items were identified in the following grids and locations. One T330 30mm HEI projectile and one T324E1 37mm HE projectile were discovered in J2N35 Area 1, and one MK61 MOD 0 HE, signal underwater sound and one MK2 37mm HE projectile were discovered in J2O30 Area 2. Only munitions debris or metallic debris were identified in J2K31 Area 1, J2K32 Area 1, J2O30 Area 1, J2P35 Areas 1 through 4, J2N35 Areas 2 through 44, and location 26 in J2O33.

In February 2013, an additional seven anomalies were investigated in grids K33 (six anomalies) and L33 (one anomaly). One munitions debris item, an empty M1 105mm projectile was found at one of the anomaly locations in grid K33 and another anomaly in this grid was designated a "No Find". The remaining five anomaly locations contained surface debris (i.e., steel plates, two pieces of sheet metal), and, in grid L33, a brick pile, rebar and construction debris. No MEC items were found in these grids.

Area 3 BIP-Related Sampling

A total of 275 soil samples were collected from 48 locations associated with BIP activities in this portion of the range. BIP sample locations, sample identification, collection date, sample depths, and laboratory analyses associated with these locations are listed in Table 3-13. Most of the BIP samples were associated with Disposal Area 2. Contaminated soils generated as a result of BIP activities were excavated as required in the BIP management program. Table 3-13 contains analytical detections for those soils excavated under the BIP management program.

Fourteen BIP-related soil samples collected from nine locations had detections of perchlorate and/or explosive compounds and remain in place. Low levels of explosives compounds remain in 13 BIP-related samples (post-BIP, supplemental BIP or post excavation BIP) collected from eight locations; J2A200600, SS04342-A, SS04343-A, SS04345-A, SS04346-A, SSJ2M30001, SSJ2M30002, and SSJ2O32006. One low level detection of perchlorate was reported in post-excavation sample SSJ2L31001 (Figure 3-20) and remains in place. Table 3-14 summarizes the detections of explosives/perchlorate in soil that remain in place.

3.4.4.3 Area 3 Source Characterization Conclusions

In Rows L30 to P31, soils with significant explosives and/or perchlorate contamination were found to be associated with Berm 5. In Rows L32 to P35, soils associated with significant explosives and/or perchlorate contamination were found at Disposal Area 2, comprised of polygon 1 and polygon 2, and the Anomaly North of polygon 2. Thirty-two burn/burial pits were found during these investigations. Note that Area 3 is the only area in which burn pits were found. These areas were addressed during soil removal actions, and with a few exceptions, no significant soil contamination remains. One location within Disposal Area 2 (SSJ2T2J) contains a low level of perchlorate at 0.37 µg/Kg. Two other locations, SSJ2M35001 (grid M35) and SSJ2MNO35C01 (grid N35) contain low levels of perchlorate (1.5 µg/Kg) and 2 amino-4,6-dinitrotoluene (130 µg/Kg). Detected results remaining in place are evaluated in the risk screen (Section 6.0). All other remaining detections are associated with BIP activities. Two locations in Area 3 (SSJ2N35010 and SSJ2N35011) required post-BIP follow-up excavation activities. All remaining detections are evaluated in the risk screen (Section 6.0).

The conceptual site model of munitions use in J-2 Range, Area 3 was developed from range characteristics, range records, review of aerial photographs, and intrusive investigation finds. The development of the conceptual site models is presented in more detail in Appendix G. The available information suggests that two distinct activities occurred in the Area 3. The area in grids L and M, rows 30 and 31, Berm 5, was the site of a munitions target berm used for munitions testing. Subsurface anomalies also suggest that some disposal activities occurred on the backside of Berm 5. The area in grids M, N, O, P rows 31, 32, 33, 34 and 35, were a known disposal area that contained MEC and was the site of a soil removal action.

A significant reduction in overall MEC has been achieved through various intrusive investigation and soil removal actions. The highest percentage of MEC items were recovered from the burial investigations. No known burials remain. Single MEC items were also discovered on the range between the investigation areas and it is possible that some may remain at isolated medium sized to small geophysical anomaly locations. It is likely that they are fragmentation, metallic debris or individual intact munitions, both inert and HE. As a result of demolition operations in the former MSP polygon 2 area, kick-outs are possible. Area 3 also lies within the down-range portion of the J-2 Range and could contain residual munitions from testing and training. These single MEC items are likely to be the 20mm projectiles, 30mm projectiles, 37mm projectiles, 40mm projectiles, and/or 57mm projectiles.

3.4.5 Area 4 – J-2 Range Extension (Rows 36-48)

The J-2 Range Extension Area (Area 4) is located in the northern portion of the J-2 Range, north of Barlow Road and encompasses Rows 36 to 48. Investigation of the J-2 Range Extension began in 2007 in response to EPA concerns about a lack of characterization of this area after several MEC items (primarily 105mm projectiles) were observed during multiple site walks that took place in October 2006. In addition, hand-held magnetometer responses were observed in areas that exhibited topographic variations, such as mounds or depressions. Finally, an assessment of historical aerial photographs identified two additional features to be investigated (ECC 2007).

Extensive field investigation activities have since been performed in the J-2 Range Extension Area. These investigations included a comprehensive detector-aided reconnaissance, vegetation clearance of support areas, UXO surface clearance, a ground-based geophysical survey, an Engineering Detection Dogs (EDD) Pilot Study (including an EDD survey of the area followed by visual and mechanical screening for energetics at select EDD detection locations), intrusive investigations at select geophysical anomaly locations, surface soil sampling, and a soil removal action. Area 4 generally lacks the extensive and diverse surface features indicative of historical contractor use and testing that are present at multiple locations in Areas 1, 2 and 3. Therefore, in the following discussion, Area 4 is considered as a whole and the discussion is not subdivided geographically by rows.

Soil sampling was primarily related to geophysical investigation finds and general site characterization activities conducted in the extension area. The J-2 Range Area 4 soil data set represents site investigations conducted from November 2007 through May 2010. A total of 195 soil samples were collected from 89 locations within this portion of the range. In most cases, samples were collected from multiple depths at each location, resulting in a larger number of samples than actual sample locations. Multiple increment samples were collected from the east and west berm areas to determine the extent of contamination at the edge of the J-2 Range. One hundred-point multiple increment samples were collected from locations SSJ2EBC01 and SSJ2WBC01 in August 2008. Additional details about soil samples collected within this area are discussed below and presented in Table 3-15. Table 3-16 summarizes analytical detections in soil that has already been excavated during various intrusive investigations, removal actions, or in conjunction with BIP activities (Figure 3-23). Table 3-17 summarizes analytical detections for all soil samples that represent current in-situ site conditions. The complete database for all soil analytical results collected through 2010 is included in Appendix F. Soil sample locations as well as locations and descriptions of MEC items identified in the field are depicted on Figure 3-21. Figure 3-22 depicts multiple increment soil sampling areas. Figure 3-23 presents excavated areas and Figure 3-24 depicts current site conditions including chemical results boxes for samples with remaining explosives or perchlorate detections.

3.4.5.1 Area 4 Findings

Composite soil samples were initially collected from three locations (SS101W, SS101X and SS101Y) in the J-2 Range Extension in an area where a piece of thermite (a pyrotechnic) was observed. These samples were non-detect for explosives compounds. During geophysical investigations, 100-point multiple increment soil samples were collected from 27 grids and from the two berm areas in order to determine the extent of contamination at the edge of the J-2 Range (Figure 3-22). Multiple increment samples were collected from the east and west berm areas to determine the extent of contamination along the edges of Area 4. A total of 70, 30-point multiple increment soil samples were also collected from 35 locations associated with Engineering Detection Dog (EDD) locations (Figures 3-21 and 3-22). Multiple increment sampling results indicated low concentrations of perchlorate in grids encompassed by Rows 35 through 42, Row 45 (grids O43, O44, and N47), and the berm samples (Figure 3-22). These detections will be evaluated in the risk screen (Section 6.0). Elevated concentrations of perchlorate, HMX, and TNT were identified in grids M44, N44, N43 and O43 (Figure 3-22).

Perchlorate was detected at 23 µg/Kg at location SSJ2ND127. HMX detections ranged from 160 µg/Kg to 33,000 µg/Kg, with the highest detection at location SSJ2O43C01 in grid O43. TNT detections ranged from 260 µg/Kg to 1,400 µg/Kg, with the highest concentration at location SSJ2ND074. Soils associated with these samples were excavated (Figure 3-23).

During the geophysical investigations, a possible demolition area was identified in grid M44 based on signs of possible "kick-out" and the condition of munitions debris discovered in the area. The area was excavated to a depth of 6 feet below ground surface. No buried munitions were identified with this feature. All MEC items found in Grid M44 were at depths between 2 and 30 inches and (see Table 2 of Appendix G) were found individually, not in one concentrated area, indicating that there is no burial pit in this location. These items include thirty-one 30mm HEI projectiles, three 60mm mortars, two 81mm mortars, and one 105mm projectile. A multiple-increment soil sample (SSJ2M4417) was collected from the base of the excavation. The sample was non-detect for explosives compounds and perchlorate. A waste characterization sample (J2M4417_STP) was collected from the excavated soil stockpile. The analytical results allowed re-using the soil as backfill in the excavation area. Two cracked open 30mm projectiles were identified in grid M44. Discrete soil samples (SSJ2M4413 and SSJ2M4412) were collected beneath these items. Sample SSJ2M4413 had RDX concentrations at 28,000 µg/Kg, perchlorate at 8,060 µg/Kg and HMX at 490 µg/Kg. Sample SSJ2M4412 had an RDX concentration of 6,500 µg/Kg (Table 3-16).

A discrete soil sample (SSJ2M4105) was also collected beneath a cracked open 105mm item. TNT, 4A-2,6 DNT, RDX and HMX were detected in the sample. Soils associated with these cracked open munitions were excavated for off-site disposal. Post-excavation samples collected from these locations were non-detect for explosives compounds and perchlorate. More than five empty suspected liquid propellant canisters, some partially buried, were identified in anomalies located on the edge of grids M44 and M45. The most visible canister contained the following stenciled information: "6M M3," "Propellant Mixture," "Flammable Liquid," "National [illegible] of Cleveland OH," "DA-01-021-ORD-5515"; with a label on top reading "Hayes Aircraft, ICC Special, Permit No. 1665, 10958". All visible canisters appeared to be empty. The items were excavated to a depth of one foot below-ground-surface. A sample (SSJ2M4501) was collected from the base of the excavation. This sample was non-detect for explosives compounds and perchlorate. However, soil in grid M44 was excavated during the J-2 Range Extension soil removal action (Figure 3-23). A discrete soil sample (SSJ2M4104) was also collected from beneath an empty propellant canister. Low levels of SVOCs (phenol at 42 µg/Kg and di-N-octylphthalate at 37 µg/Kg) were identified in the sample collected from beneath the propellant canister. These detections remain in place and are evaluated in the risk screening section (Section 6.0).

The initial investigation at the J-2 Range Extension Area consisted of a non-intrusive detector-aided reconnaissance. The reconnaissance survey was performed based on observations made during previous site walks in the area. The findings from the detector-aided reconnaissance survey are presented in the J-*2 Range Extension Area Reconnaissance – Summary and Recommendations Project Note*, dated 01 March 2007. MEC items recovered because of the reconnaissance survey are located in Table 1 and Table 2 of Appendix G. The majority of these items discovered, all of which were found at the surface, were M1 105mm projectiles with inert bodies and live fuzes (small quantity energetic). One M1 105mm HE projectile was found in grid O37. One M720 60mm inert mortar was found in grid N37 and one M374 81mm mortar was found in grid M43. Both items had inert filler and live fuzes (small quantity energetic). The results of this survey were used as the basis for the EDD pilot study and pit discrimination analysis investigations described below.

Based on the results of the detailed reconnaissance discussed above, further investigation in J-2 Range Extension was warranted and the vegetation was cleared in June 2007. Following the vegetation clearance, the ground-based geophysical and EDD Pilot Study surveys were performed. The ground-based geophysical survey was conducted in July 2007 with the Phase 1 EDD survey completed and evaluated in August 2007. The Phase 2 EDD survey was conducted in spring of 2008, which included surface soil sampling and intrusive investigation of anomalies.

Thirty-five locations were investigated as part of the EDD Pilot Study. Table 1 in Appendix G lists items found during the investigation and indicates the final disposition. The MEC items found during the investigation are included below:

- J-2 N Loc 17 contained small arms consisting of one-hundred sixteen 7.62mm bullets w/tracers(small quantity energetic).
- J-2 N Loc 18 contained small arms including one 7.62mm bullet w/tracer (small quantity energetic).
- J-2 N Loc 21 contained three grains of propellant.
- J-2 N Loc 73 contained one 3.5-inch HEAT rocket and one M374 81mm mortar with inert filler and a live fuze.
- J-2 N Loc 99 contained one T330 30mm HEI projectile.
- J-2 N Loc 125 contained three T330 30mm HEI projectiles.

Forty-eight locations were selected for intrusive investigation in Areas 4. Table 1 in Appendix G lists items that were found during the investigation and indicates the final disposition. The locations with corresponding MEC items discovered during the investigation are described below:

- Anomaly #1 contained nine powder train time fuzes and one M1 105mm projectile with inert filler and a live fuze (small quantity energetic).
- Anomaly #2 contained one M1 105mm projectile that was cracked open with exposed filler. A discrete sample was collected from beneath this item (Sample Location SSJ2M4105), which had detections of RDX (53,000 µg/Kg), HMX (43,000 µg/Kg) and TNT (3,700 µg/Kg). In addition, one M374 81mm mortar, with inert filler and a live fuze, was discovered.
- Anomaly #3 contained seven T330 30mm HEI projectiles.
- Anomaly #8 contained one T330 30mm HEI projectile.
- Anomaly #10 contained five 30mm HEI projectiles.
- Anomaly #14 contained one M374 81mm mortar with inert filler and a live fuze.
- Anomaly #15 contained one M720 60mm mortar with inert filler and a live fuze.
- Anomaly #36 contained one T330 30mm HEI projectile.
- Anomaly #45 contained one unknown smoke mixture and one 105mm illumination Candle mixture (small quantity energetic).

In accordance with the approved *Final J-2 Range Soil Removal Activities Project Note* (ECC 2009), approximately 1,110 cubic yards soil with elevated levels of explosives compounds at grid areas M44, N43, N44 and O43 were excavated, mechanically screened, and treated at the L Range treatment facility on base (Figure 3-23). Scattered single T330 30mm HEI projectiles were discovered during support area clearance work in grids M44, M45, N44, and N43.

3.4.5.2 Area 4 BIP Samples

Some suspect items discovered during intrusive field investigations, and road and well pad clearance activities, were BIP. A total of 45 samples were collected from 36 locations associated with BIP activities in Area 4. BIP sample locations, sample identification, collection date, sample depths, and laboratory analyses associated with this sub-area are identified in Table 3-15. The pre-BIP sample collected at SSJ2L4401 in grid L44 had detections of HMX and tetryl at 56 µg/Kg and 14 µg/Kg, respectively. The soil associated with this BIP location was excavated under the BIP management program. In grid M44, the pre-BIP sample collected at locations SSJ2M4402 and SSJ2M4416 had an HMX detection of 14 µg/Kg and a detection of 4A-4,6 DNT of 23 µg/Kg, respectively. The BIPs in grid M44 fell within an excavation footprint (Figure 3-23) and the associated soil was removed. The post-BIP sample from SSJ2M4304 has elevated detections of HMX, RDX, TNT, 2,4 DNT, 2A-4,6 DNT and 1,3,5 trinitrobenzene (Figure 3-24). The post BIP sample from SSJ2N3701 had elevated concentrations of TNT, HMX, RDX, perchlorate 4A-2,6 DNT and 2A-4,6 DN, and the post BIP sample from location SSJ204402 had elevated concentrations of perchlorate at 3,980 µg/Kg (Figure 3-24). Soils associated with these BIPs will be managed under the BIP management program. Post-BIP samples collected from locations SSJ2M4302, SSJ2O4601, SSJ204201, SSJ2N3602, SSJ2N3603, SSJ2N3604, SSJ2M4106 all had detections of explosives compounds or perchlorate that were below the BIP excavation criteria and therefore remain in place (Figure 3-24).

3.4.5.3 Area 4 Source Characterization Conclusions

Soil in areas with elevated explosives compounds concentrations, identified in grids M44, N44, N43 and O43, were removed for on-site treatment. Other remaining detections of explosives compounds associated with BIPs will be managed under the BIP management program. All other remaining detections are evaluated in the risk screen (Section 6).

The conceptual site model of munitions use in J-2 Range Area 4 was developed from range characteristics, range records, review of aerial photographs, and intrusive investigation finds. The development of the conceptual site models is presented in Appendix G. The available information suggests that a former disposal area existed around grids M, N in rows 43 and 44. All of Area 4 is considered to be within the downrange portion of J-2 Range and lies within the Impact Area.

Large anomalous areas identified throughout the geophysical survey were excavated. Additional locations selected through the EDD Pilot Study were investigated. Isolated medium to small sized geophysical anomalies still remain on the range and it is likely that they represent fragmentation, metallic debris, or individual munitions that could be either inert or HE. Items that could remain on the range containing HE or small quantity of energetic include M1 105mm projectiles, M72 66mm LAW rockets, M49/M720 60mm mortars, M43/M374 81mm mortars, M28 3.5-inch HEAT rockets, T330 30mm projectiles, and fuzes.

4.0 RESPONSE ACTIONS

4.1 Source Removal

Geophysical investigations, including anomaly and associated soils removals were conducted from 1997 through 2010. These activities resulted in the investigation of over 271 geophysical anomalies. These investigations resulted in the excavation and off-site disposal or on-site thermal treatment of approximately 1,110 cubic yard of soil (Table 3-5) from 34 investigation locations. In addition to the soil removals, these investigations also removed MEC from 62 locations (Table 4-1).

As previously discussed in Section 3.3, soil sampling results identified soils with elevated concentrations of explosives compounds in 15 areas of the range:

- Anomaly West of Polygon 1
- BIP Crater - J2.A.TIA.021 & 022
- Anomaly North of Polygon 2
- Berm 5
- Berm 2
- Disposal Area 1
- Disposal Area 2
    - Polygon 1
    - Polygon 2
- Twin Berms
- Fixed Firing Point 3 (FFP-3)
- 101EM/EL - Fixed Firing Point 4 (FFP-4)
- 101EJ - FFP 4
- 101EI - FFP 4
- Range Road Burn Area (RRBA)

Soils from these locations were removed as a Rapid Response Action (RRA) between April 2004 and November 2006 (Figures 3-16, 3-19). Soils with explosives detections were excavated to depths ranging from of 0.75 to 3.5 feet below ground surface and mechanically screened to remove any remaining munitions. These soils were thermally treated on-site.

Approximately 6,474 cubic yards of contaminated soil was excavated (Table 4-1). Post-excavation, five-point composite soil samples were collected in each of the excavation areas units from 0 to 3 inches below the excavation floor. All samples were analyzed for explosives and perchlorate by method SW 846/8330B and 6850. Results from post-excavation sampling indicated no detections of explosives or perchlorate exceeding the action levels. The results of this RRA are documented in the *Final J-2 Range Rapid Response Action Completion of Work Report* (ECC 2007).

As discussed in Section 3.4.6.1, additional soil sampling activities in the J-2 Extension area identified soils with elevated detections of explosives compounds, primarily HMX. In 2009 and 2010, soils with explosives detections were excavated to depths ranging from of 0.5 to 1.0 feet below ground surface and mechanically screened to remove any remaining munitions. In accordance with the approved Final J-2 Range Project Note (ECC 2009), approximately

1,110 cubic yards of soil with elevated levels of explosives compounds from grid areas M44, N44 and O43 were excavated, mechanically screened, and treated at the L Range treatment facility on base (Figure 3-23).

The soils were treated at the L Range using alkaline hydrolysis, which involves raising the pH of the soil by blending it with treatment cell water and hydrolyzed lime to degrade and mineralize the explosive compounds to more elemental compounds of inorganic nitrogen and carbon dioxide. After blending, the soils are staged in a lined treatment cell at the L Range then sampled to determine the effectiveness of treatment. Details of the excavation, confirmatory sampling, and soil treatment activities associated with the J-2 extension are presented in the *Final J-1, J-2 and Former K Ranges Soil Treatment Report* (IAGWSP 2012).

Additional geophysical investigations will be conducted at the J-2 Range. Specifically, confirmatory investigations will be conducted in the relevant grids upgradient of the J-2 East groundwater plume.

In addition, to geophysical investigations, confirmation soil sampling investigations will be conducted at the J-2 Range. Details of the proposed soil sampling program including sampling locations and analyses will be developed in a Project Note.

4.2 Groundwater Interim Response Actions

Since public water supply wells are located downgradient from the J-2 northern/J-2 eastern plumes, the response objective for the J-2 RRA was to provide accelerated protection of WS-2/WS-1 and aquifer restoration by capturing and treating contaminated groundwater until an expedited long-term remedy could be selected for the plume via the RI/FS process.

4.2.1 J-2 Northern Rapid Response Action

The nature and extent of the J-2 northern plume was initially investigated during an aquifer profile sampling program conducted in 2003–2004. This investigation revealed the existence of a longitudinally extensive plume of comingled perchlorate and RDX with perchlorate by far the dominant constituent in terms of lateral extent and concentration. The 2003–2004 investigation found that the most highly concentrated portions of the plume were located in the area along and upgradient of Wood Road. A profile sample collected from 170 feet bgs at the location of MW-289, approximately 2,000 feet south of Wood Road, measured 370 µg/L. The plume profile at this location exhibited perchlorate concentrations above 2 µg/L over a thickness of approximately 60 feet (140 to 200 feet bgs). A deeper zone of perchlorate contamination was also observed from 300 to 320 feet bgs at this profile location, where a maximum concentration of 9.2 µg/L was measured in the first sample collected from monitoring well MW-289M1. The most detailed delineation of the plume width occurred in a series of aquifer profiles installed along Wood Road, where maximum perchlorate concentrations of 45 µg/L, 89 µg/L and 42 µg/L were detected in profile samples collected between 200 and 210 feet bgs at the locations of MW-293, MW-300 and MW-305, respectively. The maximum perchlorate concentration in profile samples at MW-302 to the west was 9.5 µg/L, again at the 200 feet bgs interval. All profile samples collected at MW-331 and MW-322 were below the 2 µg/L MMCL, bounding the plume to the east and west. Figure 4-1 depicts the conceptualization of the plume at the outset of pumping.

In 2005, a rapid response action was initiated to mitigate further migration of the J-2 Range northern plume toward public water supply well WS-2. The design on the J-2 northern extraction, treatment and infiltration (ETI) system consists of three extraction wells oriented along the plume axis operating at a combined flow of 375 gallons per minute (GPM), two modular treatment units (MTUs), one stand-alone treatment system, and four infiltration trenches to return the treated groundwater to the aquifer (Figure 2-9). The treatment train (granular activated carbon [GAC], ion-exchange resin [IX], and polishing GAC) was designed for removal of RDX and perchlorate from the groundwater. The J-2 northern ETI system began operation in September 2006. The *Final J-2 Range Northern Groundwater Rapid Response Action Plan* (ECC 2006a) presents the assessment activities, modeling and well field design for the J-2 northern groundwater plume.

As of February 2013, the J-2 northern RRA system has treated over 1.2 billion gallons of contaminated groundwater and has removed more than 84 pounds of perchlorate and one pound of RDX from the aquifer. Perchlorate concentrations in groundwater samples collected from monitoring wells installed in the most highly contaminated profile intervals at all locations on Wood Road were below 2 µg/L within 1-3 years of system startup, and have maintained these diminishing trends, suggesting that the perchlorate plume was becoming segmented in response to RRA pumping or at least had become smaller than the monitoring well network (Figure 4-1, 4-2). Also within this time frame RDX was no longer being detected in samples collected in wells located downgradient of Wood Road. While diminishing perchlorate trends have been observed at some in-plume monitoring wells (MW-289, MW-348) monitoring wells installed in the immediate vicinity of extraction wells J2EW0001 and J2EW0002 (J2EW1-MW-1C and J2EW2-MW-3B, respectively) have exhibited a high degree of variability in perchlorate concentrations.

In notable contrast to the concentration variability observed in nearby monitoring wells, RRA treatment system influent perchlorate concentrations derived from extraction wells J2EW0001 and J2EW0002 have been stable, albeit at relatively elevated concentrations (between 10-15 µg/L), since system startup. This phenomenon suggests that a significant amount of unmapped contaminant mass still lies within the capture zones, especially of J2EW0001, where concentrations measured in the 75 gpm flow have ranged between 12.6 µg/L and 20.7 µg/L since system startup. The existence of this additional contaminant mass was proven through a series of aquifer profiles collected in the vicinity of J2EW0001 in 2012. These data were used in the development of an updated J-2 north perchlorate plume shell (Figure 4-2) for use in the feasibility study that is presented in sections 8 through 11 of this report and which is described in more detail in Appendix I.

4.2.2 J-2 Eastern Rapid Response Action

In May 2007 the IAGWSP and EPA agreed to proceed with construction of an ETI system as a rapid response action to mitigate migration of the J-2 eastern plume toward public water supply well WS-1. The system included three extraction wells, pumping a total of 425 GPM, four MTUs identical to those used at the J-2 northern RRA system, and three infiltration trenches (Figure 2-9). The Final J-2 Range Eastern Plume 6-Month Environmental Monitoring Report (ECC 2010) presents the system startup assessment, modeling and well field design for the J-2 eastern groundwater plume. The system began operating in August 2008. To date the J-2 eastern ETR system has treated over 950 million gallons of contaminated groundwater and has removed more than 13 pounds of perchlorate and 4 pounds of RDX from the aquifer.

The J-2 eastern plume was derived from a number of different sources and thus the nature and extent of groundwater contamination is heterogeneous. The perchlorate concentrations within and just downgradient of the source area were determined to be below 30 µg/L in 2004 and have been decreasing since (MW-307M3). These trends indicate that the source area is no longer contributing a significant amount of contaminant mass to the aquifer. The J-2 eastern plume, as defined by detectable concentrations of perchlorate, initially consisted of a main body and two flanking lobes (Figure 4-3) but currently only consists of a main lobe with the lateral flanking lobes having been largely diminished. The perchlorate plume is approximately 4,850 ft long and widens to approximately 1,800 ft at its widest point. The main body of the plume currently consists of areas of contamination primarily within each of the three extraction well (J2EW0004, J2EW0005, and J2EW0006) capture zones. The current maximum detected perchlorate concentration of 75.6 µg/L was measured at MW-368M1 in August 2012. RDX encompasses approximately the same extent in the main body of the J-2 eastern perchlorate plume but without the flanking lobes and extending slightly further downgradient of J2EW0006 (Figure 4-4). The current maximum detected RDX concentration of 17.57 µg/L was measured at MW-368M2 in August 2012. The center of the main body of the J-2 eastern perchlorate plume plunges from approximately 68 ft mean sea level (ft msl) at the source area to approximately -160 ft msl (top of bedrock) at MW-393. The plume is approximately 30 feet thick beneath the source area at MW-307 and thicker as the plume migrates downgradient (60 feet thick at MW-368 and 20 feet thick at MW-393). The leading edge of the RDX plume is slightly shallower than the perchlorate plume and extends further downgradient.

RRA treatment system influent perchlorate concentrations derived from extraction wells J2EW0004 have been relatively stable at 1 µg/L since startup in 2008, have shown an increase from 1.5 µg/L to 4.5 µg/L back to 2 µg/L from extraction well J2EW0005 and a steady decline at extraction well J2EW0006 from 1 µg/L to 0.4 µg/L. These trends correspond to upgradient concentrations and extraction rates and suggest that the perchlorate mass in the plume is reasonably well understood. RDX concentrations derived from the extraction wells is consistently less than 1 µg/L and shows relatively little upward or downward trend since startup.

These data were used in the development of an updated J-2 eastern perchlorate and RDX plume shells (Figure 4-4) for use in the feasibility study that is presented in sections 8 through 11 of this report and which is described in more detail in Appendix I.

5.0 CONCEPTUAL SITE MODEL

The conceptual site model is the depiction of site conditions that relate to contaminant source, environmental pathways for contaminants, and potential for contact with human receptors.

5.1 Source

The J-2 Range has primarily been used as a defense contractor testing range where functional and ballistic testing of various mortar and artillery munitions was conducted. Munitions assembly and disposal activities are also known to have occurred at various locations on the range. Residues from the firing activities have been found to be concentrated around firing positions and target areas. Residues from munitions testing and disposal practices have been found at various locations on the range. Groundwater contaminated with perchlorate and/or RDX has been found in areas downgradient from the J-2 Range northern and eastern areas that appears to be associated primarily with disposal and impact areas on the range. Secondary sources could include target and firing points located across the J-2 Range.

5.1.1 Northern Area

The conceptual site model (Figure 5-1), based on known activities and presence of soil contaminants, recognized one major source component in J-2 Range northern area. Soil sample results in the vicinity of Disposal Areas 1 and 2 show contaminants that are consistent with explosives and perchlorate found in downgradient groundwater. Disposal Area 2 is likely to be the primary source of the J-2 North plume. This disposal area show elevated levels of RDX and perchlorate that are consistent with the development of a nearby RDX and perchlorate plume. It is, therefore, likely that particles dispersed through disposal activities accumulated in sufficient quantities to result in groundwater contamination.

5.1.2 Eastern Area

The conceptual site model (Figure 5-1), based on known activities and presence of soil contaminants, recognizes multiple source components in J-2 Range eastern area; primarily related to the disposal and testing of munitions that would have led to soil contamination. The J-2 eastern plume has numerous potential sources, most of which have been removed, either during the 2004 RRA or through various geophysical anomaly investigations. The source of the western lobe of the J-2 eastern plume is likely Disposal Area 1. The main lobe of the J-2 eastern plume likely has numerous sources in Areas 1 and 2 and may include the following areas: 30mm HEI impact area, twin berms, FFP-3, FFP-4, RRBA, and surrounding areas. Other potential sources for the J-2 eastern plume are areas where RDX and/or perchlorate have been detected in soil samples. Many of the J-2 eastern sources were remediated during the soil RRA.

Surface soil sample results in the vicinity of grids M19/M20 show contaminants detected in soil that are consistent with explosives and perchlorate found in downgradient groundwater. Other potential sources include soil contamination from the dispersal of explosives particles near targets and firing points. Perchlorate concentrations in the vicinity of the firing points and in disposal areas in grids J16 and H13 in the eastern portions of the site have likely contributed to the groundwater contamination. The extent of the plume is consistent with a source area in this location.

5.2 Pathway

Following deposition onto the soil, precipitation will dissolve a fraction of the contaminant mass, which then migrates toward the water table. Dissolution is a function of the temperature, intensity, and duration of the precipitation, soil characteristics, drainage patterns, solubility, surface area, and kinetics. Although dissolution of the solid compounds is relatively slow, once dissolved, compounds such as RDX, HMX, and perchlorate move through the soil column with limited or minimal sorption to the soil surfaces. Other contaminants such as metals, pesticides, and PAHs move more slowly based on their chemical properties. It is, therefore, reasonable to assume that contaminants that are more easily mobilized, such as RDX and perchlorate, pose a more immediate threat to groundwater than many other potential COCs from the J-2 Range. However, all detected analytes were evaluated for their potential to leach to groundwater in the risk screen (Section 6.0).

For the northern area, releases of explosive-related contaminants in the environment have occurred, ultimately causing infiltration of certain of these contaminants to groundwater. All indications are that the primary contaminants, perchlorate and RDX, entered the groundwater with little retardation, and migrated in the direction of groundwater flow. Flow trajectories are influenced by the position of the top of the groundwater mound that is located southwest of the J-2 Range northern area. Based on the amount of recharge during a particular period, the groundwater mound can move and increase hydrodynamic dispersion (flow field tends to splay/disperse contaminants). In general, the flow trajectories are north-northeasterly in the area of the J-2 Range northern plume.

For the J-2 Range eastern area, releases of explosive contaminants to the environment have occurred, ultimately causing infiltration of certain of these contaminants to groundwater. All indications are that RDX and perchlorate entered the groundwater with little retardation and migrated in the direction of groundwater flow. Flow trajectories are influenced by the position of the top of the groundwater mound that is located just southwest at the J-1 Range area. Based on the amount of recharge during a particular period, the groundwater mound can move and increase hydrodynamic dispersion (flow field tends to splay/disperse contaminants). In general, the flow trajectories are northeasterly just downgradient of the source and in the downgradient portion of the plume flow trajectories are more northerly.

5.3 Receptors

Analysis of the potential for contaminants reaching receptors is based on hypothetical exposures to groundwater if it were drawn from monitoring wells downgradient of the J-2 Range. No one is using the groundwater in these areas and the areas downgradient are closely managed. The J-2 Range northern plume remains in the impact/firing Area so access is limited. There is, however, a public water supply well (WS-2) located approximately 0.6 mile downgradient of the J-2 Range northern plume. Water supply well WS-1 is located approximately 0.5 mile downgradient of the J-2 eastern plume. Residences in the vicinity of the J-2 Range eastern plume are connected to the municipal water system and all future residents are required to use the municipal system as well. There are no known additional potable or irrigation wells downgradient of the J-2 Range capable of being exposed to either plume.

Although residential use is not a likely future land use within MMR, hypothetical residents are identified as potential receptors to determine the need for institutional controls and to provide information for evaluating all future-use options in the Feasibility Study (FS). Therefore, hypothetical residents (on- and off-site) were identified as future receptors and the use of groundwater from the J-2 Range as a source of potable water was considered a potential exposure pathway.

Ongoing soil removal actions at the J-2 Range have removed the explosives-contaminated soil and thereby eliminated the potential for contact with contaminated soils that exceed standards.

Contaminated groundwater from the northern J-2 plume flows in a north-northeast direction. The J-2 eastern plume is more fan-shaped and consists of an elongated main lobe, which migrates in a northeasterly direction, and several smaller lobes that migrate in more easterly or northerly directions, as governed by the locations of its several originating sources along the curving water table beneath the midrange area. The soil removal actions conducted in the disposal areas, firing points, targets and J-2 extension areas will reduce contaminant mass in the source areas.

6.0 RISK SCREENING

6.1 Introduction

Risk screening evaluations were conducted for J-2 Range. The objective of the risk screening was to identify any contaminant of concern (COC) detected in the J-2 Range groundwater and soil that requires further evaluation. The risk screening for soil included an evaluation of the potential for analytes detected in the soils to leach from the soil and migrate through the subsurface to the groundwater.

6.2 Groundwater Evaluation

A total of 185 monitoring wells at 76 locations associated with J-2 Range eastern and northern plumes were identified for use in compiling the groundwater risk screening data set. These wells are listed in the footnotes of Table 6-1. The data set includes analytical results for samples collected from 1997 to February 2012 for all detected analytes. Profile and drive-point sample results, and certain extraction well data (i.e., for J2EW0001, 0002, 0003) were not included. The groundwater analytical program included explosives, perchlorate, metals and inorganics, pesticides, herbicides, SVOCs, VOCs, and PCBs. The full set of groundwater sampling results for the J-2 Range eastern and northern plumes are presented in Appendices D-1 and D-2, respectively.

Table 6-1 presents the results of the risk screening evaluation that was performed on the combined J-2 Range groundwater data set. The maximum concentration of each detected analyte was compared to its federal and Massachusetts (where available) Maximum Contaminant Level (MCL or MMCL), EPA Drinking Water Health Advisory (HA), EPA Regional Screening Level (RSL) for Tapwater, and MCP Method 1 GW-1 Standard. Other factors that were considered in the risk screening to determine whether to further evaluate the detected analyte included whether the analyte was an essential human nutrient, its frequency of detection, specific characteristics of the analyte, and if the compound had a documented history of false positive analytical results. The subsections that follow summarize the results of these comparisons and considerations for the groundwater associated with the J-2 Range by chemical group.

A discussion of the significant findings of the groundwater screening process is provided in the following sections.

6.2.1 Explosives

Nineteen explosives were analyzed for by Method 8330 in groundwater samples from 185 sampling points. Three additional explosives were occasionally included in the analytical program for 21 of the wells (i.e., hexahydro-1-mononitroso-3,5-dinitro-1,3,5-triazine (MNX), hexahydro-1,3-dinitroso-5-mononitro-1,3,5-triazine (DNX), and hexahydro-1,3,5-trinitroso-1,3,5-triazine (TNX)). Eleven explosives were detected in at least one groundwater sample. Three explosives were detected only once (2-nitrotoluene, 3-nitrotoluene and picric acid). As these detections were not repeated in subsequent sampling events at the same locations, these explosives compounds were not considered further in the groundwater risk screening evaluation. Of the eight explosives that were detected on more than one or two occasions, the noted groundwater screening criteria were exceeded only for RDX, 2,4,6-TNT, and 2,4-DNT. All of the detections of 2,4,6-TNT and 2,4-DNT were observed at a single location, MW-234, at the M1 and M2 screened intervals.

Five monitoring wells are located within the known footprint of the northern RDX plume and nine monitoring wells are located within the known footprint of the eastern RDX plume. Since 1997, exceedances of the most stringent screening criterion for RDX (the RSL of 0.61 µg/L) have been observed at least once in 11 of the monitoring wells associated with the J-2 Range northern plume. Since 2009, exceedances of the RSL have been observed in only four of these monitoring wells (i.e., J2EW1-MW1-C, MW-230M2, MW-234M1 and MW-289M2), and the maximum observed RDX concentration since 2009 was 4 µg/L. Since 1997, exceedances of the RSL for RDX have been observed at least once in the 18 monitoring wells associated with the J-2 eastern plume. Since 2009, exceedances of the RSL have been observed in ten of these monitoring wells (i.e., J2MW-01M2, J2MW-04M1, MW-215M2, MW-228M2, MW-321M2, MW-324M1, MW-324M2, MW-335M1, MW-368M1, and MW-368M2), and the maximum RDX concentration observed since 2009 was 15.4 µg/L. As such, RDX was retained for further evaluation.

6.2.2 Perchlorate

Perchlorate was detected in approximately 41% of all J-2 groundwater samples analyzed and in 124 of the 185 sampling points. Eight monitoring wells are located within the known footprint of the northern perchlorate plume and 10 monitoring wells are located within the known footprint of the eastern perchlorate plume.

Since 1997, exceedances of the most stringent screening criterion for perchlorate (the MMCL and MCP GW-1 Standard of 2 µg/L) have been observed at least once in 18 of the monitoring wells associated with the J-2 Range northern plume. Since 2009, exceedances of perchlorate have been observed in only six of these monitoring wells (i.e., J2EW1-MW1-B, J2EW1-MW1-C, J2EW2-MW3-B, J2EW3-MW-2-C, MW-289M2, and MW-313M2), and the maximum observed perchlorate concentration since 2009 was 198 µg/L (by Method 6860). Since 1997, exceedances of the MMCL and MCP GW-1 Standard for perchlorate have been observed at least once in 15 of the monitoring wells associated with the J-2 eastern plume. Since 2009, exceedances of perchlorate have been observed in nine of these monitoring wells (i.e., J2MW-01M2, J2MW-04M1, MW-215M2, MW-307M3, MW-310M1, MW-335M1, MW-324M1, MW-368M1, and MW-368M2), and the maximum perchlorate concentration observed since 2009 was 87.5 µg/L (by Method 6860; the duplicate sample result by Method 6860 was 86.1 µg/L). As such, perchlorate was retained for further evaluation.

6.2.3 Metals and Inorganics

Thirty-one metals and inorganics were analyzed for in samples from 61 of the 185 sampling points used to construct the groundwater data set, and all were detected at least once. However, only arsenic, chromium (total), cobalt, manganese, mercury, nitrogen (as nitrate-nitrite), and thallium exceeded any of their respective screening criteria. The most recent sampling event for metals and inorganics was November 2005, with the exception of tungsten, which was included in the April 2007 sampling and analysis program.

Arsenic was detected in 7 of the 277 samples included in the groundwater data set. The maximum detected concentration of arsenic in groundwater was an estimated 5.6 µg/L (from sampling point MW-63M1), which exceeded the HA and RSL, but was below the MCL and MCP GW-1 Standard of 10 µg/L. Furthermore, many studies have been conducted to characterize the elevated levels of arsenic in groundwater throughout New England. Naturally occurring arsenic is common in alluvial aquifers of the United States (Korte 1991). Chromium (total) was detected in 19 of 277 samples. The maximum detected concentration of chromium was 12.1 µg/L in a sample from sampling point MW-63S that was collected on September 21, 1999. Chromium has only been sporadically detected in 15 different wells, typically only once per well. The maximum detected concentration of chromium exceeded the RSL for hexavalent chromium for Tapwater, but was less than the RSL for trivalent chromium, and its MCL and the MCP GW-1 Standard. Cobalt was detected in 22 of 277 samples, three of which exceeded the RSL. More recent sampling events from these locations were non-detect for cobalt. Manganese was widely detected, but only seven sampling points had exceedances of its HA (300 µg/L) and its RSL (320 µg/L). In addition, subsequent results for manganese from the same sampling point (i.e., MW-18S) were all below the RSL. Mercury was only sporadically detected, and the maximum detected concentration (0.64 µg/L) barely exceeded its RSL (0.63 µg/L) and was below its MCL and its MCP GW-1 Standard. There were only seven detections of thallium in groundwater, with a maximum reported concentration that was estimated to be 4.7 µg/L. This same concentration was reported for samples taken from MW-48D on June 26, 2000 and from MW-49S on November 11, 1999. Thallium has not been detected in the subsequent rounds of sampling conducted at either of these sampling points. The maximum detected concentration of nitrogen measured as nitrate-nitrite (3,300 µg/L) exceeded the MCL for nitrite (1,000 µg/L) and the RSL for nitrite (1,600 µg/L), but not the MCL for nitrate (10,000 µg/L). The maximum detected concentration also did not exceed the RSL for nitrate or the HA for nitrate plus nitrite. Therefore, arsenic, chromium, cobalt, manganese, mercury, thallium, and nitrogen as nitrate-nitrite in groundwater were determined to not warrant further evaluation.

Tungsten was detected in 2 of 8 samples included in the groundwater data set (the only groundwater samples that were analyzed for tungsten). There are currently no published groundwater protection screening criteria for tungsten. For the purposes of this screening evaluation, a screening level of 730 µg/L was calculated using the U.S. Army Center for Health Promotion and Preventive Medicine (CHPPM) oral RfD of 0.02 mg/Kg-day (CHPPM 2007) and the same equation and assumptions that were used to develop the EPA risk-based RSLs for Tapwater for the other listed chemicals. The MassDEP Office of Research and Standards has identified a chronic interim RfD for tungsten of 0.0028 mg/Kg-day. Using this chronic interim RfD, MassDEP has developed an interim drinking water standard of 20 µg/L (MassDEP 2006). Since the maximum detected concentration of tungsten (an estimated 0.83 µg/L) was well below these calculated risk-based screening values, tungsten in groundwater does not appear to present a risk to human health based on the current toxicology. In addition, most tungsten detections prior to 2007 are suspected to be false positives due to problems that were being experienced with the analytical method that had been used at that time. Tungsten has not been detected in groundwater at the J-2 Range since 2003.

Four of the detected inorganics had no published screening criteria from the established sources, but are considered to be essential human nutrients (i.e., calcium, magnesium, potassium, and sodium). As such, they were not considered for further evaluation. In summary, therefore, no metals or inorganics in the groundwater were identified as warranting further evaluation relative to the J-2 Range.

6.2.4 Pesticides and Herbicides

Twenty-one pesticides and 18 herbicides were analyzed for in groundwater samples from 59 of the 185 sampling points used to construct the groundwater data set. Three pesticides and eleven herbicides were occasionally reported as detected in these groundwater samples, but the frequency of detection was less than 2% for all of these detected pesticide and herbicide compounds. Only the maximum detected concentrations for two of these compounds (i.e., MCPP and pentachlorophenol) exceeded any of their respective screening criteria. MCPP and pentachlorophenol were detected only once and twice, respectively, in the groundwater risk screening data set samples. Furthermore, the MCPP detections have been associated with false positives obtained with an old analytical method that is no longer used (AMEC 2002a). The analyses for herbicides performed prior to 2001 have been shown to be affected by interferences that have led to tentative identifications and estimated quantifications of MCPA and MCPP. In 2001, modifications were made to the analytical method for herbicides to minimize these interferences. As such, the analytical data for this compound obtained prior to 2001 likely represent false positive results. There have been no detections of MCPP since 2000, and no detections of any pesticide or herbicide compound in groundwater samples analyzed after 2002. Therefore, no pesticides or herbicides in the groundwater were identified as warranting further evaluation.

6.2.5 Semivolatile Organic Compounds

Eighty SVOCs were analyzed for in groundwater samples from 64 of the 185 sampling points used to construct the groundwater data set. The most recent sampling event for SVOCs was November 2005. Of the 80 SVOCs that were analyzed, four phthalate esters (i.e., bis(2-ethylhexyl)phthalate, diethyl phthalate, di-n-butyl phthalate, and di-n-octyl phthalate), benzoic acid, carbon disulfide, and naphthalene were detected. Of these seven SVOCs, the maximum detected concentration of only bis(2-ethylhexyl)phthalate (at an estimated 3,300 µg/L in MW-57S on December 21, 1999) and naphthalene (at an estimated 0.38 µg/L in MW-154M1 on July 24, 2001) exceeded any of the chemical-specific groundwater screening criteria. Bis(2-ethylhexyl)phthalate is a probable laboratory contaminant, as evidenced by its sporadic detection and the relatively high variation in measured concentrations. For example, the duplicate field sample result for sampling point MW 57S on December 21, 1999 (the sampling point and date for which the maximum was noted) was reported as non-detect and bis(2-ethylhexyl)phthalate was not detected in five of the six subsequent sampling efforts. In addition, while certain phthalates are sometimes associated with munitions components, bis(2-ethylhexyl)phthalate is not one of these (AMEC 2001). None of the other phthalates sometimes associated with munitions exceeded any of their screening criteria. Three of the four reported detections for naphthalene were associated with samples from MW-154M1 and the fourth was associated with a sample from MW-154S. Naphthalene has not been detected in either of these wells during subsequent sampling events. Therefore, SVOCs were not considered further in the groundwater screening evaluation.

6.2.6 Volatile Organic Compounds

Forty-five VOCs were analyzed for in samples collected from 94 of the 185 sampling points used to construct the groundwater data set. The most recent sampling event for VOCs was December 2006. Of these 45 VOCs, only 11 of the compounds were detected in the groundwater and only two of these 11 exceeded at least one of their groundwater screening criteria: chloroform and trichloroethene. Chloroform was detected in 79 wells, and its degradation product (chloromethane) also was detected in 16 wells. In all cases, the reported concentrations of chloroform exceeded the lowest of its groundwater screening criteria (i.e., the EPA RSL for Tapwater of 0.19 µg/L), but were below its MCL, HA, and MCP GW-1 Standard. In addition, chloroform appears to be ubiquitous within the portion of the aquifer being studied.

Chloroform, which has not been identified as a compound associated with historical J-2 Range activities, has been widely observed in groundwater across the Upper Cape, and has been determined to be naturally present in much of the groundwater on Cape Cod (Earth Tech 2000). Thus, chloroform and its degradation product, chloromethane, were not retained for further investigation. TCE was detected in one well, but the detected concentration was below the MCL and MCP GW-1 Standard. Therefore, VOCs were not considered further in the groundwater screening evaluation.

6.2.7 Polychlorinated Biphenyls

PCBs were analyzed for in samples collected from 54 of the sampling points used to construct the groundwater data set. One of the seven Aroclors that were analyzed for (Aroclor 1254) was detected in two groundwater samples. Subsequent groundwater samples collected at each of the two wells where PCBs had been detected were non-detect for all PCBs. Although the maximum detected concentration of PCBs exceeded its HA and the RSL, it was less than the MCL and the MCP GW-1 Standard. Therefore, PCBs were not considered further in the groundwater screening evaluation.

6.2.8 Summary of Site-Wide Groundwater Screening

Groundwater data from monitoring well sampling points associated with the J-2 Range were available for explosives, perchlorate, metals and inorganics, pesticides and herbicides, SVOCs, VOCs, and PCBs. Of the 220 analytes reported for groundwater, 19 were detected at maximum concentrations that exceeded one or more risk-based groundwater screening criteria: 2,4-DNT, 2,4,6-TNT, 2-nitrotoluene, RDX, perchlorate, arsenic, chromium, cobalt, manganese, mercury, nitrogen (as nitrate-nitrite), thallium, MCPP, pentachlorophenol, bis(2-ethylhexyl)phthalate, naphthalene, chloroform, TCE, and Aroclor 1254. Of the detected explosives compounds reporting exceedances of at least one screening criterion, only RDX continues to be detected at elevated concentrations and with a frequency of detection that indicates a potential risk to groundwater use. All of the detections for 2,4,6-TNT and 2,4-DNT were observed at a single location, MW-234, at the M1 and M2 screened intervals. 2-Nitrotoluene was only detected once in over 1,500 samples, and was not detected in subsequent samples from the same sampling points where the exceedance had been previously reported. Perchlorate also was seen to pose a potential threat to groundwater. Of the metals and inorganics reporting exceedances of screening criteria, the presence of arsenic is not indicated to be related to operations at the J-2 Range. Chromium has only been sporadically detected, and the maximum detected concentration of chromium (total) was less than its MCL and the MCP Method 1 GW-1 Standard. Three of the 22 detections of cobalt exceeded the RSL. More recent sampling events from these locations were non-detect for cobalt. Although manganese was widely detected, only a small number of the detected concentrations exceeded its RSL and subsequent sampling results for this same sampling point no longer exceeded the criteria. Mercury was only sporadically detected, and the maximum detected concentration barely exceeded its RSL and was below its MCL and its MCP GW-1 Standard. The maximum detected concentration of nitrogen (measured as nitrate-nitrite) (3,300 µg/L) exceeded the MCL for nitrite (1,000 µg/L), but not the MCL for nitrate (10,000 µg/L). The maximum detected concentration also did not exceed the RSL for either nitrite or nitrate or the HA for nitrate plus nitrite. Thallium was infrequently detected and was not detected in the subsequent rounds of sampling at the same sampling point where the exceedance was measured. MCPP and pentachlorophenol were detected only once and twice, respectively, and were not detected in later sampling events at either monitoring well. In addition, the MCPP detection is likely to be a false positive due to the application of an analytical method that is no longer used. Bis(2-ethylhexyl)phthalate detections are believed to have been a laboratory artifact or unrelated to munitions components associated with the J-2 Range. Three of the four reported detections for naphthalene were for MW-154M1 and the fourth was for MW-154S. Naphthalene was not detected in either of these two wells during subsequent sampling events. Chloroform is indicated to be present in groundwater due to natural sources, and not related to activities at the J-2 Range. TCE has been detected in only one well, but the detected concentrations were below the MCL and MCP GW-1 Standard. Although Aroclor 1254 was reportedly detected twice, subsequent samples from each of the two wells where the detections were reported were non-detect for PCBs. Although the maximum detected concentration of Aroclor 1254 exceeded its HA and the RSL, it was less than the MCL and the MCP GW-1 Standard. Based on the screening analysis performed for the J-2 Range groundwater, perchlorate and RDX were identified as COCs in both the J-2 northern and eastern groundwater plumes and will be further evaluated in the Feasibility Study.

6.3 Soil Evaluation

For purposes of the soil screening evaluation, the J-2 Range was divided into the following four discrete sub-areas based on the range use:

- Area 1 (Rows 10 to 17, Column H through M)
- Area 2 (Rows 15 to 29, Columns M through O)
- Area 3 (Rows 30 to 35)
- Area 4 (Rows 36 to 48)

As noted in section 4.0, soil contaminated with explosives and perchlorate have been treated on-site or removed off-site in a series of response actions. The analytical detections evaluated in the risk screen represent current site conditions. Tables 6-2 through 6-5 present comparisons of the maximum detection concentrations in currently remaining soil to a series of screening values for the J-2 Range soil sub-areas. The screening values included the MCP Method 1 S-1/GW-1 Standards, the MassDEP leaching based soil concentrations, the MMR SSLs, and the EPA risk-based SSLs. It is noted that the MCP Method 1 S-1/GW-1 standards were used as screening criteria only for those analytes for which values have been published in 310 CMR 40.0975(6)(a). The background level for screening purposes is the MMR background value (AMEC 2001). Other considerations evaluated in the screening evaluation included whether an analyte was a human nutrient, the detection frequency of that analyte, and background levels. The frequency of detection is not used as the sole criteria for the elimination of a compound for further consideration.

6.3.1 Area 1 Firing Points/Melt Pour Facility (Rows 10 to 17)

Table 6-2 presents the comparisons to the screening criteria for Area 1.

6.3.1.1 Explosives Compounds and Perchlorate

Eight explosives compounds (2,4-DNT, 2,6-DNT, 4-amino-2,6-DNT, RDX, nitroglycerin, TNT, 1,3-diethyl-1,3-diphenyl urea, and tetryl) and perchlorate were detected in Area 1 soils (Table 6-2). The maximum detected concentration for the majority of these compounds exceeded at least one screening value. Of these, only perchlorate and RDX have been detected in J-2 East groundwater monitoring wells. Only one compound (2,4-DNT) exceeded the S-1/GW-1 standard (0.7 mg/Kg), in the vicinity of the N Range firing line. Only two other samples, both from location SS165B, contained 2,4-DNT concentrations greater than the MCP

S-1/GW-1 standard (0.87 mg/Kg and 1.0 mg/Kg). Only 2,4-DNT, 1,3-diethyl-1,3-diphenyl urea, and perchlorate were detected in more than three samples.

1,3-Diethyl-1,3-diphenyl urea was detected in the soil but had no screening values and it was not detected in the groundwater. Based on these findings explosives compounds in Area 1 soils will not be evaluated in the Feasibility Study.

6.3.1.2 Metals and Inorganics

As presented on Table 6-2, a number of metals and inorganics were detected in the Area 1 soil. The maximum detected concentrations of a number of metals exceeded at least one of their respective screening levels. However, the site concentrations for the majority of the metals were similar to or were less than background levels. The exceptions to this were copper and zinc which are discussed in more detail below.

- Copper – the maximum concentration (1,810 mg/Kg) exceeded the MMR SSL and the EPA risk-based SSL. The average concentration (22 mg/Kg) was less than the SSLs. It was detected in the groundwater but below levels of concern.

- Zinc – the maximum concentration (1,320 mg/Kg) exceeded the EPA risk-based SSL. The average concentration (49 mg/Kg) was well below the SSL. It was detected in the groundwater at levels consistent with background concentrations.

Only the maximum detected concentrations of lead and nickel exceeded their respective S-1/GW-1 standards. In addition to the maximum detected concentration, only one other sample exceeded the MCP S-1/GW-1 standard for chromium (31.5 mg/Kg at SS101Q) and two other samples exceeded the MCP S-1/GW-1 standard for cadmium (4.7 mg/Kg at Target 32 and 2.9 mg/Kg at SS11092-A). These exceedances are not within a contiguous area.

Although most metals were detected in J-2 East groundwater monitoring wells, only thallium was detected at concentrations greater than MCLs of GW-1 standards. Thallium was detected in Area 1 soils at concentrations exceeding SSLs, but only two locations slightly exceeded background levels. Based on these findings, none of the metals and inorganics were evaluated in the Feasibility Study.

6.3.1.3 PAHs

Several PAHs were detected in the Area 1 soil. The PAHs were detected sporadically throughout Area 1. The frequency of detections ranged from 4% to 49%. The maximum detected concentrations of ten PAHs exceeded at least one of their respective screening values. However, there were no exceedances of the MCP S-1/GW-1 standards. With the exception of naphthalene, none of the PAHs were detected in the groundwater. The concentration of naphthalene in the groundwater was below levels of concern. The site concentrations of the PAHs were less than or similar to background levels. Based on these findings, the PAHs in Area 1 soils will not be evaluated in the Feasibility Study.

6.3.1.4 Pesticides and Herbicides

Several pesticides and herbicides were detected in the Area 1 soil. The frequency of detections ranged from 1% to 63%. The maximum detections of 18 compounds exceeded a screening value. However, none were reproducibly detected in groundwater above levels of concern. The distribution and concentration of pesticides and herbicides in Area 1 soils are presumed to be consistent with application in accordance with manufacturer's guidelines. Based on these findings, these compounds will not be evaluated in the Feasibility Study.

6.3.1.5 VOCs, SVOCs, and PCBs

Several VOCs, SVOCs, and PCBs were detected in the soil (Table 6-2). The analytes were detected sporadically throughout the site at frequencies of detection ranging from <1% to 38%.

- VOCs – The maximum detected concentrations of several VOCs exceeded at least one of their respective screening values. However, none exceeded their MCP S-1/GW-1 standards, and none were detected in groundwater above levels of concern.
- SVOCs – The maximum detected concentrations of a few SVOC exceeded the screening values, however, none were detected in groundwater and, with the exception of 2,4-dimethylphenol, all were below the MCP S-1/GW-1 standard. There was only a single detection of 2,4-dimethylphenol out of 185 samples analyzed.
- PCBs – Two PCBs (1254 and 1260) exceeded the MMR SSL and the EPA risk-based SSL. However, they were detected relatively infrequently and were below the MCP S-1/GW-1 standard.

Based on these findings, the VOCs, SVOCs, and PCBs in Area 1 soils will not be evaluated in the Feasibility Study.

6.3.1.6 Polychlorinated Napthalenes

PCNs were detected in the soil by Method 8270 with Selected Ion Monitoring (SIM). The presence of the PCNs is associated with their use as inert fillers in some mortar and/or artillery rounds. PCNs were detected in 19 of 57 samples. Tetra- and tri-chlorinated naphthalenes accounted for 59% of the PCNs detected in these samples. Penta-chlorinated naphthalenes accounted for a further 22% of the PCNs detected in samples. The higher chlorinated PCNs (hexa-, hepta- and octa-) were detected in a limited number of samples, contributing 14% to the overall number of PCNs detected. Research on the relative potencies of these compounds indicates that naphthalenes with four or fewer chlorines or eight chlorines do not have apparent "TCDD-like" toxicity (AMEC 2001). At least some of the penta-, hexa-, and hepta-chlorinated-naphthalenes do have a mechanism of toxicity that is similar to TCDD although to a much lesser degree than TCDD. The cited letter proposed that relative experimental potency (REP) factors be assigned to the penta-, hexa- and hepta-chlorinated naphthalenes based upon the published cellular assays (AMEC 2001). These REPs were used to adjust screening criteria for TCDD as follows:

- Penta-chlorinated naphthalenes have REP factors of approximately 10^{-4} suggesting they are on the order of 10,000 times less toxic than TCDD; and
- Hexa- and hepta-chlorinated naphthalenes have REP factors of approximately $3x10^{-3}$ suggesting they are on the order of 300 times less toxic than TCDD.

The maximum detected concentrations of penta-, hexa-, and hepta-chlorinated-naphthalenes exceeded the adjusted screening criteria. Most of the reported detections and the highest reported concentrations were in samples from grid M16. As noted in Section 3.4.3, this area was used by contractors for testing and disposal.

As the number of chlorines increases, the solubility decreases from 17 mg/L for 1-chloronaphthalene to 0.0004 mg/L for tetra-chloronaphthalene to 0.00008 mg/L for octa-chloronaphthalene. These compounds also absorb strongly to organic particulate matter, with log K_{oc}s estimated for tetra-chlorinated-naphthalenes at 4.15 and at 4.36 for penta-chlorinated-naphthalenes. The higher chlorinated, more toxic PCNs deposited on the soil surface would not be expected to have sufficient mobility to impact groundwater at the site (AMEC 2001). The maximum detected concentrations of penta-, hexa-, and hepta-chlorinated-naphthalenes exceeded the REP-adjusted screening criteria. PCNs have historically been addressed under the BIP protocols. Based on this, the PCNs in Area 1 soils will not be evaluated in the FS.

6.3.2 Area 2 Firing Points/Testing/Disposal Area (Rows 15 to 29)

Table 6-3 presents the comparisons to the screening criteria for Area 2.

6.3.2.1 Explosives Compounds and Perchlorate

Ten explosives compounds (2,4-DNT, 2,6-DNT, 2-amino-4,6-DNT, 4-amino-2,6-DNT, HMX, Nitroglycerin, RDX, penta-erythritol tetranitrate, 1,3-diethyl-1,3-diphenyl urea, TNT) and perchlorate were detected in Area 2 soils (Table 6-3). The maximum detected concentrations for the majority of these compounds exceeded at least one screening value. However, except for RDX, perchlorate, and 1,3-diethyl-1,3-diphenyl urea, the frequency of detection for explosives compounds were 1% or lower and only HMX, RDX and perchlorate exceeded the MCP S-1/GW-1 standard as further discussed below:

- HMX – exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, the MMR SSL, and the EPA risk-based SSL. It was detected in eight of 689 samples (FOD = 1%). It was not detected in the groundwater. Only one sample exceeded the MCP S-1/GW-1 standard (sample location SSJ2SG004) with an HMX detection of 10 mg/Kg.

- RDX – exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, the MMR SSL, and the EPA risk-based SSL. It was detected in 27 of 48 samples (FOD = 56%) and was detected in the groundwater. Four samples exceeded the MCP S-1/GW-1 standards. Location SS04170-A (2.8 mg/Kg) and OG071900-03_21 (5.6 mg/Kg) are associated with BIPs and will be excavated under the BIP protocols. The other two detections of RDX exceeding the standards were in sample locations SSJ2M19005_PE1 (2.0 mg/Kg) and SSJ2M19005_PE3 (1.8 mg/Kg) collected from the 1.0 to 1.25-foot interval from an area that was below the limits of the subsequent 2009 excavation. However, subsequent post-excavation surface multiple increment sample results were non-detect for RDX (Sample locations SSJ2M1911 and SSJ2M2012).

- Perchlorate – exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, and the MMR SSL. It was detected in 84 of 270 samples. Thirty-four of the detected concentrations exceeded the MassDEP leaching concentration. Twenty-nine of the detected concentrations exceeded the MMR SSL. It was also detected in the groundwater. Only two of the detected concentrations exceeded the MCP S-1/GW-1 standard. Both of these samples were associated with post-BIP sample SSJ2M19005. However, the multiple increment samples collected from this grid (SSJ2M1911 and SSJ2M2012) had perchlorate detections well below the standards.

Two explosives compounds (1,3-diethyl-1,3-diphenyl urea and pentaerythritol tetranitrate) were detected in the soil but had no screening values. Locations with RDX detection exceedances of S-1/GW-1 standards associated with BIP activities (sample locations SS04170-A and OG071900-03_21) will be excavated under the BIP protocols.

Based on these findings explosives compounds in Area 2 soils will not be evaluated in the Feasibility Study.

6.3.2.2 Metals and Inorganics

As presented on Table 6-3, a number of metals and inorganics were detected in the Area 2 soil. The maximum detected concentrations of a number of metals exceeded at least one of their respective screening levels. However, the site concentrations for the majority of the metals were similar to or were less than background levels. The exceptions to this were copper, lead, and zinc, which are discussed in more detail below.

- Copper – the maximum concentration (8,940 mg/Kg) exceeded the MMR SSL and the EPA risk-based SSL. The average concentration (58 mg/Kg) was marginally greater than the SSLs. However, only 49 of the 354 detected concentrations exceeded the MMR SSL and 74 exceeded the EPA risk-based SSL. This indicates that copper is not present at elevated levels across Area 2. It was detected in the groundwater but below levels of concern.

- Lead – the maximum concentration (1,040 mg/Kg) exceeded the MCP S-1/GW-1 standard and the MMR SSL. However, the average concentration (22 mg/Kg) was less than the MCP S-1/GW-1 standard. Only two of the detected concentrations exceeded the MCP S-1/GW-1 standard. Nearly all of the detected concentrations exceeded the MMR SSL. Lead was detected in the groundwater at levels consistent with background concentrations.

- Zinc – the maximum concentration (1,930 mg/Kg) exceeded the EPA risk-based SSL and only three of the 365 detected concentrations exceeded the EPA SSL. The maximum detection was below the MMR SSL and the MCP S-1/GW-1 standard. This indicates that zinc is not present at elevated levels across Area 2. It was detected in the groundwater at levels consistent with background concentrations.

In addition to the maximum detected concentration, only one other sample exceeded the MCP S-1/GW-1 standard for chromium (54 mg/Kg at Target 10), and one other sample exceeded the MCP S-1/GW-1 standard for nickel (4.7 mg/Kg at Target 10). In addition to the maximum detected concentration, four samples from three other locations exceeded the MCP S-1/GW-1 standard for cadmium. These exceedances are not within a contiguous area.

Although most metals were detected in J-2 East groundwater monitoring wells, only thallium was detected at concentrations greater than MCLs or GW-1 standards. Thallium was detected in Area 2 soils at concentrations exceeding SSLs, but only the maximum detected concentration slightly exceeded background levels.

Based on these findings, none of the metals and inorganics in Area 2 soils will be evaluated in the Feasibility Study.

6.3.2.3 PAHs

Several PAHs were detected in the Area 2 soil. The PAHs were detected sporadically throughout Area 2. The frequency of detections ranged from <1% to 40%. The maximum detected concentrations of nine PAHs exceeded at least one of their respective screening values. With the exception of naphthalene, none of the PAHs was detected in the groundwater. The concentration of naphthalene in the groundwater was below levels of concern. The site concentrations of the PAHs were less than or similar to background levels and all were below the MCP S-1/GW-1 standards. Based on these findings, the PAHs in Area 2 soils will not be evaluated in the Feasibility Study.

6.3.2.4 Pesticides and Herbicides

Several pesticides and herbicides were detected in the Area 2 soil. The frequency of detections ranged from <1% to 67%. The maximum detections of 15 compounds exceeded a screening level. However none were detected in groundwater above levels of concern. The distribution and concentration of pesticides and herbicides are presumed to be consistent with application in accordance with manufacturer's guidelines. Based on these findings these compounds in Area 2 soils will not be evaluated in the Feasibility Study.

6.3.2.5 VOCs, SVOCs, and PCBs

Several VOCs, SVOCs, and PCBs were detected in the soil (Table 6-3). The analytes were detected sporadically throughout the site. There were no exceedances of the MCP S-1/GW-1 standards. The following analytes that were observed in the Area 2 soil (see Table 6-3) exceeded at least one the screening values:

- VOCs – The maximum detected concentrations of several VOCS exceeded at least one of their respective screening criteria. However, none exceeded the MCP S-1/ GW-1 standards, and none were detected in groundwater above levels of concern.
- SVOCs – The maximum detected concentration of carbazole, bis(2-ethylhexyl)phthalate (BEHP) and n-nitrosodiphenylamine exceeded at least one of the available screening criteria but as presented in Table 6-3, none exceeded the MCP S-1/GW-1 standard. The presence of BEHP appears to be an artifact of the investigation methods where it was introduced to the samples from plastic equipment used during collection and analysis.
- PCBs – Two PCBs (1254 and 1260) exceeded the MMR SSL and the EPA risk-based SSL. However, they were detected infrequently (FOD = <2%) and were below the S-1/GW-1 standard.

Based on these findings and no exceedances of the MCP S-1/GW-1 standard, the VOCs, SVOCs, and PCBs in Area 2 soils will not be evaluated in the Feasibility Study.

6.3.2.6 Dioxins and Furans

Dioxins and furans were detected in Area 2. Evaluated as 2,3,7,8-tetrachlorodibenzo-p-dioxin toxic equivalents (2,3,7,8-TCDD TEQ) (USEPA 2009), the maximum concentration exceeded the MMR SSL and the EPA risk-based SSL. However, the TEQ does not exceed the MCP S-1/GW-1 standard. The presence of the dioxins and furans is associated with isolated burn/burial pits. All identified burn/burial pits have been removed, and based on the findings of the munitions source assessment (Appendix H), additional burn/burial pits are unlikely in this portion of the range. Therefore, dioxins and furans are not expected to be widely present at the J-2

Range. Based on these findings, the dioxins and furans in Area 2 soils will not be evaluated in the Feasibility Study.

6.3.2.7 Polychlorinated Naphthalenes

PCNs were detected in 93 of the 164 locations sampled. Tetra- and tri-chlorinated-naphthalenes accounted for 49% of the PCNs detected in these samples. Penta-chlorinated-naphthalenes accounted for a further 23% of the PCNs detected in samples. The higher chlorinated PCNs (hexa-, hepta- and octa-) were detected in a limited number of samples, contributing 16% to the overall number of PCNs detected. PCNs were detected in the soil in samples primarily associated with BIP activities. The presence of the PCNs is associated with their use as inert fillers. As a result, they are not expected to be widely present on-site. The PCN detections are evaluated under the BIP program in the BIP Summary Reports. The maximum detected concentrations of penta-, hexa-, and hepta-chlorinated-naphthalenes exceeded the REP-adjusted screening criteria. The higher chlorinated, more toxic PCNs deposited on the soil surface would not be expected to have sufficient mobility (due to their insolubility and tendency to absorb strongly to organic particulate matter) to impact groundwater at the site (AMEC 2001). PCNs have historically been addressed under the BIP protocols. Based on this, the PCNs in Area 2 soils will not be evaluated further.

6.3.3 Area 3 Disposal Area (Rows 30 to 35)

Table 6-4 presents the comparisons of the detection concentrations to a series of screening values for Area 3.

6.3.3.1 Explosives Compounds and Perchlorate

Nine explosives compounds (2,4-DNT, 2-amino-4,6-DNT, 4-amino-2,6-DNT, HMX, nitroglycerin, 2-nitrotoluene, RDX, tetryl, TNT) and perchlorate were detected in Area 3 soils (Table 6-4). The maximum detected concentrations for the majority of these compounds exceeded at least one screening value and their frequencies of detection were 6% or lower. The majority of the locations with exceedances of screening values are BIP related samples that were below the BIP excavation criteria. Additionally, none of the compounds exceeded the MCP S-1/GW-1 standards. Based on these findings explosives compounds in Area 3 soils will not be evaluated in the Feasibility Study.

6.3.3.2 Metals and Inorganics

As presented on Table 6-4, a number of metals and inorganics were detected in the Area 3 soil. The maximum detected concentrations of a number of metals exceeded at least one of their respective screening levels. However, the site concentrations for the majority of the metals were similar to or were less than background levels. The exceptions to this were copper, lead, and zinc that are discussed in more detail below.

- Copper – the maximum concentration (2,860 mg/Kg) exceeded the MMR SSL and the EPA risk-based SSL. The average concentration (48 mg/Kg) was marginally greater than the SSLs. Only 13 of the 143 detected concentrations exceeded the MMR SSL and the EPA risk-based SSL. This indicates that copper is not present at elevated levels across Area 3. It was detected in the groundwater but below levels of concern.

- Lead – the maximum concentration (942 mg/Kg) exceeded the MCP S-1/GW-1 standard and the MMR SSL. (This BIP location was subsequently excavated and a post-excavation multiple increment sample collected in November 2012 indicated a residual lead concentration of 11 mg/Kg.) The average concentration (26 mg/Kg) was less than the MCP S-1/GW-1 standard. Only two of the 141 detected concentrations exceeded the MCP S-1/GW-1 standard. Lead was detected in the groundwater at levels consistent with background concentrations.

- Zinc – the maximum concentration (23,800 mg/Kg) exceeded the MCP S-1/GW-1 standard, the MMR SSL, and the EPA risk-based SSL. (This BIP location was subsequently excavated in May 2006.) However, the average concentration (232 mg/Kg) was well below these levels. Only two of the 112 detected concentrations exceeded the MCP S-1/GW-1 standard and the MMR SSL and only three detected concentrations exceeded the EPA risk-based SSL. This indicates that zinc is not present at elevated levels across Area 3. It was detected in the groundwater but below levels of concern.

Only the maximum detected concentration of arsenic exceeded the MCP S-1/GW-1 standard. In addition to the maximum detected concentration, only one other sample exceeded the MCP S-1/GW-1 standard for cadmium (3.1 mg/Kg at SS15189-A). These exceedances are not within a contiguous area.

Although most metals were detected in J-2 North groundwater monitoring wells, only thallium was detected at concentrations greater than MCLs or MCP GW-1 standards. Thallium was detected in Area 3 soils at concentrations exceeding SSLs, but only the maximum detected concentration slightly exceeded background levels.

Based on these findings, none of the metals and inorganics in Area 3 soils will be evaluated in the Feasibility Study.

6.3.3.3 PAHs

Several PAHs were detected in the Area 3 soil. The PAHs were detected sporadically throughout Area 3. The FOD values ranged from 2% to 9%. The maximum detected concentrations of six PAHs exceeded at least one of their respective screening values. None of the PAHs were detected in the J-2 North groundwater. The presence of the PAHs is attributed to areas containing asphalt. The site concentrations of the PAHs were less than or similar to background levels, and none exceeded the MCP S-1/GW-1 standard. Based on these findings, the PAHs in Area 3 soils will not be evaluated in the Feasibility Study.

6.3.3.4 VOCs and SVOCs

Several VOCs and SVOCs were detected in the soil. The analytes were detected sporadically throughout the site. The following VOCs and SVOCs that were observed in the Area 3 soil (see Table 6-4) exceeded at least one of the screening values:

- VOCs – The maximum detected concentrations of several VOCs exceeded at least one of their respective screening criteria. However, none exceeded the MCP S-1/ GW-1 standards, and none were detected in groundwater above levels of concern. Detections of benzene and chloromethane exceeded the MMR SSL and the EPA risk-based SSL. These isolated detections are associated with BIP activities and were allowed to remain in place under the BIP protocols.

- SVOCs – N-Nitrosodiphenylamine exceeded both the MMR SSL and the EPA risk-based SSL. It was detected in four of 46 samples. It was not detected in the groundwater. The location with the maximum detection (SSJ2N35010) is a post-BIP sample that will be excavated under the BIP protocols. All other detections were below the MCP S-1/GW-1 standard.

Based on these findings, the VOCs and SVOCs in Area 3 soils will not be evaluated in the Feasibility Study.

6.3.3.5 Polychlorinated Naphthalenes

Polychlorinated naphthalenes (PCNs) were detected in the soil by Method 8270C. PCNs were detected in 13 of the 31 locations sampled. Tetra- and tri-chlorinated-naphthalenes accounted for 67% of the PCNs detected in these samples. Penta-chlorinated-naphthalenes accounted for a further 12% of the PCNs detected in samples. The higher chlorinated PCNs (hexa-, hepta- and octa-) were detected in a limited number of samples, contributing 13% to the overall number of PCNs detected. All of the detections of PCNs were in samples from Grids M30 and O31. The presence of the PCNs is associated with their use as inert fillers, and all samples analyzed for PCNs were associated with BIP activities. As a result, they are not expected to be widely present on-site. The PCN detections are evaluated under the BIP program in the BIP Summary Reports. The maximum detected concentrations of penta-, hexa-, and hepta-chlorinated naphthalenes exceeded the REP-adjusted screening criteria. The higher chlorinated, more toxic PCNs deposited on the soil surface would not be expected to have sufficient mobility (due to their insolubility and tendency to absorb strongly to organic particulate matter) to impact groundwater at the site (AMEC 2001). PCNs have historically been addressed under the BIP protocols. Based on this, the PCNs in Area 3 soils will not be evaluated in the FS.

6.3.4 Area 4 J-2 Range Extension (Rows 36 to 48)

Table 6-5 presents the comparisons of the detected concentrations to a series of screening values for soil Area 4.

6.3.4.1 Explosives Compounds and Perchlorate

Ten explosives compounds (2,4-DNT, 2-amino-4,6-DNT, 4-amino-2,6-DNT, HMX, 2-nitrotoluene, 3-nitrotoluene, RDX, tetryl, 1,3,5-trinitrobenzene, TNT) and perchlorate were detected in Area 4 soils (Table 6-5). The maximum detected concentrations for the majority of these compounds exceeded at least one screening value. The frequencies of detection for explosives compounds was generally low (<5%) with the exception of perchlorate that was detected in 38% of the samples. HMX, RDX and perchlorate were the only compounds to exceed the MCP S-1/GW-1 standard as further discussed below:

- HMX – exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, the MMR SSL and the EPA risk-based SSL. It was detected in 11 of 146 samples (FOD = 8%). It was detected in the J-2 North groundwater but was below levels of concern. In addition to the maximum detection, there was one other detection of HMX exceeding the MCP S-1/GW-1 standards (SSJ2N4101 at 2.5 mg/Kg) in a post-BIP sample that will be managed under the BIP protocols.

- RDX – exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, the MMR SSL, and the EPA risk-based SSL. It was detected in seven of 146 samples

(FOD = 5%) and was detected in the groundwater. The four detections of RDX exceeding the MCP S-1/GW-1 standards were associated with BIP samples and will be excavated under BIP protocols. These locations include SSJ2M4304 (RDX at 130 mg/Kg), location SSJ2N4101 (RDX detected at 18 mg/Kg) and location SSJ2N3701 (RDX detected at 1.2 mg/Kg and 2.2 mg/Kg).

- Perchlorate – exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, and the MMR SSL. It was detected in 45 of 119 samples (FOD = 38%). Only one of the detected concentrations exceeded the MCP S-1/GW-1 standard. Four of the detected perchlorate concentrations exceeded the MMR SSL. Five of the detected perchlorate concentrations exceeded the MassDEP leaching concentration and it was detected in the groundwater. The one detection of perchlorate exceeding the MCP S-1/GW-1 standard (SSJ204402 at 3.98 mg/Kg) is a post-BIP sample that will be managed under the BIP protocols.

Based on these findings, explosives compounds in Area 4 soils will not be evaluated in the Feasibility Study.

6.3.4.2 Metals and Inorganics

As presented on Table 6-5, a number of metals and inorganics were detected in the Area 4 soil. The maximum detected concentrations of a number of metals exceeded at least one of their respective screening levels. However, the site concentrations for the majority of the metals were similar to or were less than background levels. The exceptions to this were copper and lead which are discussed in more detail below.

- Copper – the maximum concentration (23,500 mg/Kg) exceeded the MMR SSL and the EPA risk-based SSL. The next highest concentration of copper was 911 mg/Kg. The average concentration (1,165 mg/Kg) also exceeded the SSLs. Only 50% of the detected concentrations exceeded the MMR SSL and the EPA risk-based SSL. This indicates that copper is not present at elevated levels across Area 4. It was detected in the groundwater but below levels of concern.

- Lead – the maximum concentration (5,030 mg/Kg) exceeded the MCP S-1/GW-1 standard and the MMR SSL. (This BIP location was subsequently excavated and supplemental and post-excavation multiple increment samples were collected in November 2012 with resulting lead concentrations of 20.5 and 10 mg/Kg.) The average concentration (259 mg/Kg) was less than the MCP S-1/GW-1 standard. Only the maximum detected concentration exceeded the MCP S-1/GW-1 standard. It was detected in the groundwater at levels consistent with background concentrations.

In addition to the maximum detected concentration, only one other sample exceeded the MCP S-1/GW-1 standard for chromium (46.2 mg/Kg at SSJ2O4601), and only the maximum detected concentration exceeded the MCP S-1/GW-1 standard for nickel. In addition to the maximum detected concentration, two other samples exceeded the MCP S-1/GW-1 standard for cadmium (5.5 mg/Kg at SSJ2O4402 and 3.2 mg/Kg SSJ2O4601). These exceedances are not within a contiguous area.

Although most metals were detected in J-2 North groundwater monitoring wells, only thallium was detected at concentrations greater than MCLs or MCP GW-1 standards. Thallium was detected in Area 4 soils at concentrations exceeding SSLs, but all detected results were within background levels. Based on these findings, none of the metals and inorganics in Area 4 soils will be evaluated in the Feasibility Study.

6.3.4.3 PAHs

Several PAHs were detected in the Area 4 soil. The PAHs were detected sporadically throughout Area 4. The frequency of detections values ranged from 4% to 27%. The maximum detected concentrations of three PAHs exceeded at least one of their respective screening values. None of the PAHs were detected in the groundwater and the site concentrations of the PAHs were less than or similar to background levels. Based on these findings, the PAHs in Area 4 soils will not be evaluated in the Feasibility Study.

6.3.4.4 VOCs and SVOCs

Several VOCs and SVOCs were detected in the soil. The analytes were detected sporadically throughout the site. The following VOCs and SVOCs that were observed in the Area 4 soil (see Table 6-5) exceeded at least one screening value:

- BEHP – the maximum detected concentration of BEHP exceeded EPA SSL, but was less than the MMR SSL and the MCP S-1/GW-1 standard.
- 1,2-Dichloroethane – the single detected result exceeded the MCP S-1/GW-1 standard, the MassDEP leaching concentration, and the EPA risk-based SSL. This sample is associated with BIP activities and will be managed under BIP protocols.
- Hexachlorobenzene – the single detected concentration exceeded the MMR SSL and the EPA risk-based SSL. It was detected in one of 26 samples (FOD = 4%). It did not exceed the MCP S-1/GW-1 standard and was not detected in the groundwater.
- N-Nitrosodiphenylamine – the single detected concentration exceeded the MMR SSL but was below the MCP S-1/GW-1 standard and was not detected in the groundwater.

Based on these findings, the VOCs and SVOCs in Area 4 soils will not be evaluated in the Feasibility Study.

6.3.5 Soil Evaluation Summary

Most of the soil samples with explosives and perchlorate detections exceeding screening values were associated with BIP activities and therefore will be managed under BIP protocols.

Detections of 2,4-DNT in Area 1 exceeding the MCP S-1/GW-1 standard (0.7 mg/Kg), were identified in the vicinity of the N Range firing line. In addition to the maximum detected concentration (1.2 mg/Kg at SS101Q), only two other samples, both from location SS165B, contained 2,4-DNT concentrations greater than the MCP S-1/GW-1 standard (0.87 mg/Kg and 1.0 mg/Kg, respectively).

Detections of RDX in Area 2 exceeding the MCP S-1/GW-1 standard (1.0 mg/Kg) were identified in sample locations SS04170-A (2.8 mg/Kg) and OG071900-03_21 (5.6 mg/Kg) which are associated with BIPs and will be excavated under the BIP protocols. Two other exceedances in sample locations SSJ2M19005-PE1 (2.0 mg/Kg) and SSJ2M19005_PE3

(1.8 mg/Kg) were also observed. Perchlorate detections exceeding the MCP S-1/GW-1 standard were associated with samples SSJ2M19005_PE17 (0.153 mg/Kg) and SSJ2M19005_PE18 (0.121 mg/Kg). However, subsequent multiple increment sample results in these grids were non-detect for RDX and below the MCP S-1/GW-1 and MMR SSL values for perchlorate (sample locations SSJ2M1911 and SSJ2M2012).

There were no exceedances of MCP S-1/GW-1 standards for explosive and perchlorate observed in Area 3.

Detections of HMX in Area 4 exceeding the MCP S-1/GW-1 standard (2.0 mg/Kg) were observed in two samples (SSJ2M43034 at 14 mg/Kg and SSJ2N4101 at 2.5 mg/Kg), which are post-BIP samples that will be managed under the BIP protocols. The four detections of RDX exceeding the MCP S-1/GW-1 standards were associated with BIP samples and will be excavated under BIP protocols. These locations include SSJ2M4304 (RDX at 130 mg/Kg), location SSJ2N4101 (RDX detected at 18 mg/Kg) and location SSJ2N3701 (RDX detected at 1.2 mg/Kg and 2.2 mg/Kg). The one detection of perchlorate exceeding the MCP S-1/GW-1 standard (SSJ204402 at 3.98 mg/Kg) is a post-BIP sample that will be managed under the BIP protocols.

Based on the BIP protocols and the multiple increment sampling results, explosive compounds and perchlorate in soils will not be further evaluated in the Feasibility Study. No other soil detections warrant further evaluation as part of the J-2 Range Feasibility Study.

7.0 INVESTIGATION FINDINGS

The following presents the summary and findings of the J-2 Range remedial investigation.

7.1 Groundwater Contamination

A total of 203 monitoring wells have been installed at 80 locations during groundwater investigations conducted within and downgradient of the J-2 Range. For the purposes of groundwater evaluation, the J-2 northern and eastern groundwater evaluations are discussed separately and include observations of plume behavior under active treatment as seen through the monitoring data up to December 2012. Although the plumes have similar flow directions (northerly) and plume contaminants, they are emanating from different portions of the range and resulted from different sources.

7.1.1 Northern Area

The J-2 northern groundwater plume consists of both perchlorate and RDX (Figures 2-10 and 3-1). The overall centerline length of the perchlorate plume, as defined by perchlorate above the MMCL (2 µg/L), is approximately 8,100 feet, extending from the source area downgradient to approximately 2,750 feet downgradient of extraction well J2EW0003 and the plume is approximately 860 feet wide at its widest point. Prior to the startup of the J-2 northern groundwater RRA treatment system, the J-2 northern perchlorate plume extent had been mapped as much as 7,800 feet long and 2,300 feet wide. Through a combination of mass removal via the J-2 Range northern plume RRA system and natural attenuation, the overall breadth of the perchlorate plume has decreased significantly. Decreases in perchlorate concentrations to below the 2 µg/L MMCL in areas immediately downgradient of extraction wells, including all wells along Wood Road, suggest that the perchlorate plume has become segmented in response to active treatment. Perchlorate concentrations in the vicinity of the source area (Disposal Area 2) have also decreased below the MMCL since removal of the source in 2004. However, perchlorate concentrations in wells in the immediate vicinity of J2EW001 continue to fluctuate over a wide range (from 1.8 µg/L in 2007 to 198 µg/L in 2011 to 0.76 µg/L in 2012 at J2EW1-MW-1C) suggesting the presence of localized hot spots within the plume. In addition, perchlorate concentrations in treatment system influent samples have remained between 10 µg/L and 15 µg/L since system startup suggesting that a significant amount of perchlorate mass remains in the aquifer.

The extent of the main RDX plume has diminished to the point where concentrations of RDX above 0.6 µg/L were detected in only two well samples collected in 2012. Concentrations of 2.6 µg/L and 1.9 µg/L were detected in MW-289M2 and J2EW1-MW-1C, respectively. These wells are approximately 1,500 feet apart (Figure 3-8). RDX was also detected in three profile samples at BH-585 (now MW-585), immediately upgradient of J2EW0001, at concentrations up to 1.8 µg/L. The historic maximum RDX detection of 16.1 µg/L was measured in the source area at MW-234M2 in 2008. This well has seen a steady decline in RDX concentrations since then and was below 0.6 µg/L for the first time in 2012. The extent of the RDX plume as defined by concentrations above the HA (2 µg/L), is likely less than 1,500-feet long and 200-feet wide at the widest point. Thus, RDX in groundwater has not migrated as far downgradient as perchlorate, and is completely enveloped by the perchlorate plume upgradient of J2EW0001.

The Conceptual Site Model based on known range use activities and the presence of soil contaminants suggests disposal activities, including burial and burning at Disposal Area 2, as the major source of the J-2 Range northern plume.

7.1.2 Eastern Area

The primary site-related contaminants in the J-2 Range eastern groundwater study area are also RDX and perchlorate (Figure 2-10 and 3-1). Perchlorate contamination has been detected in the main body of the plume as well as in several smaller lobes of contamination. The overall centerline length of the perchlorate plume, as defined by perchlorate above the MMCL (2 µg/L), is approximately 4,250 feet, extending from the source area downgradient to approximately 180 feet upgradient of extraction well J2EW0006 and the plume is approximately 1,700 feet wide at its widest point (Figure 2-10). The main body of the plume has also become slightly segmented due to the operation of the J2 Eastern ETI system. Although perchlorate concentrations in the central portion of the plume between MW-368 and MW-335 remain elevated, most recently 45 µg/L to 75.6 µg/L (MW-368M1/M2, respectively), this portion of the plume lies within the capture zone of the J-2 eastern treatment system. To the east of the main plume are several smaller lobes of contamination, two of which have concentrations exceeding the MMCL (Figure 3-1). Low concentrations of perchlorate (below the 2 µg/L MMCL) that lie beyond the capture zone of J2EW0006 are expected to attenuate before reaching downgradient monitoring well MW-436.

The overall centerline length of the RDX plume, as defined by the 0.6 µg/L contour, is approximately 5,800 feet, extending from the source area downgradient to approximately 1,650 feet downgradient of extraction well J2EW0006 and the plume is approximately 1,150 feet wide at its widest point. The main body of the RDX plume has also become segmented due to the operation of the J2 Eastern ETI system. The core of the RDX plume is roughly coincident with the core of the perchlorate plume with recent concentrations of 5.6 µg/L and 17.6 µg/L in MW-368M1/M2, respectively.

The Conceptual Site Model, based on known range use activities and presence of soil contaminants, suggests munitions testing and disposal activities as the major source of the eastern plume.

7.1.3 Groundwater Risk Screening

A human health risk screening was conducted for the J-2 Range groundwater. The objective of the risk screening was to identify any contaminant detected in the J-2 Range northern and eastern groundwater that requires further evaluation. The maximum detected concentration of each analyte was compared against its MCL, HA, RSL or GW-1 standard. The screening identified a widespread presence of RDX and perchlorate at concentrations exceeding the screening criteria. Therefore, RDX and perchlorate will be further evaluated in the Feasibility Study. Other compounds were identified at concentrations exceeding some risk screening criteria, but these compounds were detected infrequently, are associated with naturally occurring background conditions, or are laboratory-related contaminants and therefore were not carried forward to the feasibility study.

7.2 Source

During the period from 1997 through 2009, 3,178 soil samples were collected from 753 locations within the J-2 Range investigation area. In addition, numerous intrusive investigations of geophysical anomalies were conducted. Results of soil investigations in Disposal Area 2 show soil contamination that is consistent with explosives and perchlorate in groundwater in the

J-2 northern plume. This area is located in Area 3 and the explosives and perchlorate soil contamination associated with this source area has been removed as discussed in Section 4.0.

The primary sources of groundwater contamination in the eastern area were firing, testing and disposal areas including the Range Road Burn Areas, FFP-3, FFP-4, FFP-5, the Twin Berms, Berm 2, Disposal Area 1, grids in and around M19/M20, and disposal pits found in Grids I12, I16, J16 and H17. Explosives contaminated soil associated with these sources has been removed as discussed in Section 4.0.

For the soil risk screen, J-2 Range soil data was divided into four discrete subareas, based on the conceptual site model for the different portions of the range. The risk screen identified concentrations of 2,4 DNT, HMX, RDX and perchlorate detections exceeding the screening criteria. However, the subareas averages did not exceed the S-1/GW-1 standards. In addition, many of these locations are associated with BIP activities and soil either was allowed to remain in-place under BIP protocols or is scheduled for removal under this program. Other contaminants were occasionally detected above screening levels but only at low frequencies. Based on the above findings, there is no further action warranted for soils at the J-2 Range.

Intrusive investigations identified multiple MEC disposal areas in the northern and midrange portions of the J2 Range. These MEC disposal areas have been the basis of significant MEC clearance and soil removal actions. General Disposal activities occurred throughout the J-2 Range and were associated with the munitions testing. The T330 30mm projectiles were HE and found concentrated within the southern portion of the midrange area. These items have also been found randomly scattered throughout the range. The vast majority of mortars found were inert, or inert-bodied, with live fuzes, some HE models were discovered. Based on the geophysical investigations, remaining geophysical anomalies are likely munitions debris or other metallic debris. However, there is the potential for residual MEC items, likely consisting of inert projectiles with live fuzes or isolated individual HE items.

8.0 J-2 RANGE FEASIBILITY STUDY

The feasibility study portion of this report presents the evaluation of alternatives to remediate the RDX and perchlorate groundwater plumes at the J-2 Range areas. The sources of contamination have been removed during the investigation phase resulting in the on-site treatment or off-site disposal of approximately 9,700 cubic yards of soil.

The remedies evaluated in the J-2 Range groundwater feasibility study were monitored natural attenuation and focused extraction. These remedies include technologies implemented as part of the J-2 and J-3 rapid response actions (ECC 2006a), and evaluated in the feasibility study for Demolition Area 1 (AMEC 2004). The technology selected for the active remediation alternatives comparison is groundwater extraction, treatment with granular activated carbon (GAC) (for RDX contaminated groundwater) and/or ion-exchange resin (IX) (for perchlorate-contaminated groundwater) and return of treated water back into the aquifer. With GAC adsorption process, groundwater contaminated with explosives is passed through a carbon medium and explosives are adsorbed onto the surface of, or partition into the carbon particles. GAC has also been shown to be an effective treatment for low levels of perchlorate (below 6 µg/L) (AMEC 2004). Once the capacity of the GAC has been exhausted, the GAC requires regeneration or disposal. IX is a physical-chemical process by which ions, such as perchlorate, are transferred from the liquid phase to the solid phase. Similar to GAC treatment, treatment with IX resin occurs via flow through a porous media. The IX resin removes perchlorate ions from the water and exchanges it for chloride ions bound to the resin. Perchlorate is an anion, which is attracted to the positively charged surface of the IX resins.

The return of treated water back to the aquifer can be accomplished by various methods (e.g., reinjection wells, infiltration trenches, surface water discharge). For the feasibility study, infiltration trenches were used conceptually to return water to the aquifer. The specific method will be determined during the well field review and design effort if the selected remedy involves additional treatment.

The following steps were taken to identify alternatives to address the contamination in the J-2 plumes: (1) response action objectives were developed, (2) alternatives were developed to address the objectives, and (3) alternatives were subjected to a detailed assessment based on nine criteria (protection of human health and the environment; compliance with regulations; long-term effectiveness and permanence; reduction of toxicity, mobility or volume; short-term effectiveness; implementability; cost; state acceptance and community acceptance).

9.0 DEVELOPMENT OF ALTERNATIVES

9.1 Response Action Objectives

This section describes the response action objectives and potential response actions for J-2 Range groundwater. Based on preliminary information relating to types of contaminants, environmental media of concern, and potential exposure pathways, response action objectives were developed to aid in the development and screening of alternatives. The response action objectives for the selected response action for the J-2 Range groundwater plumes are to restore the useable groundwater to its beneficial use wherever practicable; within a timeframe that is reasonable given the particular circumstances of the site; to provide a level of protection in the aquifer that takes into account that the Cape Cod Aquifer (including the Sagamore Lens), is a sole source aquifer that is susceptible to contamination; and to prevent ingestion and inhalation of groundwater containing COCs (perchlorate and RDX), in excess of federal maximum contaminant levels (MCLs), Health Advisories, drinking water equivalent levels (DWELs), applicable State standards or an unacceptable excess lifetime cancer risk or non-cancer Hazard Index.

RDX concentrations in groundwater between 6 and 0.6 µg/L, are currently equivalent to the 10^{-5} to 10^{-6} risk based level. The NCP uses a risk range of 10^{-6} to 10^{-4} as a “target range” to manage cancer risks as part of a CERCLA cleanup. The 10^{-6} risk level serves as the point of departure for determining remediation goals for alternatives when ARARs are not available. The EPA lifetime Health Advisory for RDX is 2 µg/L. The MCP GW-1 Standard for RDX is 1 µg/L. The perchlorate MMCL is 2 µg/L and the EPA Interim Lifetime Health Advisory for perchlorate is 15 µg/L.

9.2 Regulatory Considerations

Table 9-1 summarizes the federal and state regulatory considerations for the proposed J-2 Range groundwater remedial actions.

9.3 Remedial Alternatives

Remedial alternatives were developed that included:

- A no action alternative to serve as a baseline for alternative comparisons.
- An alternative that, throughout the entire groundwater plume, reduces the contaminant concentrations to background conditions.
- An alternative that, throughout the entire groundwater plume, reduces the contaminant concentrations to level that meet or exceed the MCLs, health advisories, DWELs, other relevant standards, results in a Hazard Index of 1 or less, and a cumulative 10^{-6} excess cancer risk and non-cancer Hazard Risk of one as rapidly as possible and in less than 10 years and shall require no long-term maintenance.

A range of alternatives from no further action to focused extraction of the J-2 Range plumes are considered in this is feasibility study. Contaminated soil has been removed and remediated; therefore, the range of alternatives does not include any further source area remediation or control. The source area remediation can be considered a part of each alternative.

This section presents the remedial alternatives developed to address contamination at J-2 Range. The northern plume groundwater alternatives are:

- Alternative 1 – No Further Action;
- Alternative 2 – Monitored Natural Attenuation and Land Use Controls;
- Alternative 3 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (continued operation of current system);
- Alternative 4 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (optimization of current system);
- Alternative 5 – Focused Extraction with Four Wells. Monitored Natural Attenuation and Land Use Controls.

The eastern plume groundwater alternatives are:

- Alternative 1 – No Further Action;
- Alternative 2 – Monitored Natural Attenuation and Land Use Controls;
- Alternative 3 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (continued operation of current system);
- Alternative 4 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (optimization of current system);
- Alternative 5 – Focused Extraction with Five Wells. Monitored Natural Attenuation and Land Use Controls.

Alternative 1 for both plumes only includes well abandonment and site closeout.

Monitoring and land-use controls are components of Alternatives 2 through 5. Land-use controls consist of measures that would prevent human exposure to plume contaminants or interference with monitoring and/or treatment systems. Land Use Controls can be considered in three categories: (i) those that relate to the property that is under the control of the Army through the existing lease between the Commonwealth of Massachusetts and the US Army (i.e. on-post administrative controls), (ii) those that relate to property that is not under the control of the Army (i.e. off-post institutional controls), and (iii) those that relate to the Post after the lease with the Army has expired (i.e. post-lease institutional controls). On-post Land Use Controls would be established by the Army, Massachusetts National Guard, and any other entity in control of the on-post areas. The program would include monitoring the effectiveness of the institutional controls.

For off-post Land Use Controls, the Town of Sandwich has established regulations to protect human health. The Town of Sandwich Board of Health amended its private well regulations on 11 April 2005 to prohibit the construction of potable water supply wells for new buildings located in known and documented areas of groundwater contamination if the Sandwich Water District Service is available. For existing buildings, the Board of Health will not approve any new well to be used for human consumption until its water has been tested and the Board of Health has determined that the water is potable. Additional water testing and special standards may be required by the Board of Health if the well is located in an area of potential contamination.

In addition to the Town of Sandwich Board of Health well regulations, the Army will also assess all private wells relative to potential exposure to the J-2 Range eastern groundwater plume. If a potential exposure is identified, the Army will take action to insure protectiveness. The actions may include well decommissioning, health warnings, supplemental water supply, or treatment. Monitoring of these restrictions and controls will be conducted annually.

If cleanup levels are not attained by the end of the lease with the selected alternative, the Army would develop Land Use Controls that would be implemented after the expiration of the Army's lease.

Monitoring would involve periodic analysis of groundwater for RDX and perchlorate to measure the attenuation of the contaminated groundwater, and to confirm that concentrations have decreased below risk-based concentrations. Prior to the termination of the proposed activities, a residual risk-assessment will be conducted pursuant to a work plan approved by EPA, in consultation with MassDEP, to determine if RDX and perchlorate concentrations remaining in the aquifer pose unacceptable human health risks.

The extraction alternatives for the northern (Figure 9-1) and eastern (Figure 9-2) areas consist of: (1) extraction of groundwater through extraction well/s, (2) treatment of the groundwater through a modular treatment unit (MTU) [The MTU uses IX to remove perchlorate from the groundwater and GAC to remove explosives from the groundwater], and (3) infiltration of treated water to the aquifer via infiltration trench(es).

Each of the alternatives reduces contaminant concentrations to background conditions. In addition, the J-2 Range northern plume Alternative 5 and J-2 Range eastern plume Alternative 5 were designed to reduce the contaminant concentration to levels that meet or exceed regulatory and risk-based standards in less than 10 years after the start of treatment.

10.0 DETAILED ANALYSIS OF ALTERNATIVES

10.1 Introduction

The following subsections describe the conceptual design criteria for detailed analysis of each alternative. This section provides a description of the criteria for detailed analysis, groundwater modeling results, and the detailed analysis of the groundwater alternatives. Each alternative is evaluated against the same criteria established by the EPA and discussed below.

10.2 Criteria for Detailed Evaluation

Relative performance of each alternative is evaluated using the following nine criteria:

1. Overall protection of human health and the environment; this shall include prevention of the movement of contaminants into the aquifer and its preservation as a public drinking water supply.

2. Compliance with regulations, including:
   - Federal regulations; and
   - State regulations.

3. Long-term effectiveness and permanence, considering:
   - The risks remaining after completion of the remedial action; and
   - The adequacy and suitability of controls, if any, that are used to manage untreated contaminants remaining at the site.

4. Reduction of toxicity, mobility, and volume through treatment, including:
   - The expected reduction in toxicity, mobility or volume measured as a percentage or order of magnitude; and
   - The type and quantity of treatment residuals that will remain following treatment.

5. Short-term effectiveness, including:
   - Protection of the community during the remedial action;
   - Protection of workers during the remedial action;
   - Environmental impacts to natural resources; and
   - Time until remedial response objectives are achieved.

6. Implementability, considering:
   - Technical feasibility, including:
     - Construction and operation;
     - Reliability of technology;
     - Ease of undertaking additional remediation, if necessary; and
     - Monitoring considerations, addressing the ability to monitor adequately the effectiveness of the remedy and the risks should monitoring be insufficient to detect a system failure.
   - Administrative feasibility:
   - Availability of services and materials, including:

- o Availability of adequate off-site treatment, storage capacity, and disposal services;
- o Availability of necessary equipment and specialists, and any other necessary resources;
- o The potential for obtaining competitive bids (especially for innovative technologies); and
- o Availability of prospective technologies.

7. Cost, considering:
   - Source removal costs;
   - Capital costs, both direct and indirect;
   - Annual O&M costs; and
   - Present worth analysis (or net present value) of costs.

   The cost estimates for the alternatives include capital, annual and periodic costs associated with the anticipated scope of the alternative. These generally include construction costs, operations and maintenance (O&M) costs, system monitoring costs, and reporting costs. When possible, costs were based on actual costs for similar activities performed previously at the MMR. The general assumptions made for the present value calculations are that costs based on current year (present day) information will escalate at a rate of five percent per year until year zero. After year zero, costs were discounted at a rate dependent on the length of the alternative (2013 Discount rates for OMB Circular No. A-94). A detailed presentation of the cost estimates and present value calculations are provided in Appendix H.

8. State Acceptance, considering the issues and concerns that the State may have regarding each alternative. This criterion will be evaluated throughout the development, screening and evaluation of alternatives based on comments and input received from MassDEP.

9. Community Acceptance, which entails an evaluation of issues and concerns the public, may have regarding each alternative. This criterion will be evaluated throughout the development, screening and evaluation of alternatives based on comments and input received from the MMRCT and public.

10.3 Feasibility Study Groundwater Modeling

Estimates of the J-2 Range northern and eastern groundwater alternatives' performance were developed based on review of various data and groundwater modeling results. Treatment plant inflow rates and measured influent contaminant concentrations were used to calculate the amount of mass that has been removed by the treatment systems. Model-predictions of mass removal were determined using results from the most recent J-2 Range northern and eastern groundwater plume modeling efforts. The revised plume shells presented herein were developed to revise historic plume shells developed in support of the Final J-2 Range North Groundwater Rapid Response Action 2007 Annual System Performance Monitoring Report (ECC 2009) and the Final J-2 Range Eastern Plume 6-Month Interim Environmental Monitoring Report (ECC 2010). The conceptualizations of the J-2 Range northern and eastern groundwater plume Alternative 4 were developed based on review of the 2012/2013 plume nature and extent, the modeling conducted in support of J-2 Range Groundwater Remedial Investigation and Feasibility Study presented here, and the most recent J-2 Range northern and eastern groundwater plume modeling efforts. Review of these various resources was also used to estimate the time for perchlorate and RDX, in the relatively high hydraulic conductivity portions of the aquifer, to decrease to various concentration levels and to estimate when contaminant concentrations at the extraction wells would fall below reporting limits (Table 10-1).

The effect of an increased groundwater extraction rate on capture zones of adjacent ETR systems was also considered in the overall groundwater evaluation. It was concluded that, because the aquifer at the J Ranges is so productive, increased pumping has a noticeable but relatively minor effect on adjacent capture zones. The capture zones increase at wells with increased groundwater extraction and can expand to the point that they shift the groundwater divides away from the wells with increased rates toward the adjacent systems, but the systems are far enough apart so that contamination remains captured by the intended systems. Extraction rates would need to be increased to impractical levels before contamination from an adjacent plume would be extracted by wells in non-intended ETR systems.

10.4 Northern Area Feasibility Study

The following sections provide the J-2 Range northern groundwater modeling activities and results, and the detailed description and analysis of the remedial alternatives. Each alternative description includes assumptions made for planning and cost-estimating purposes. For the northern plume, the alternatives are evaluated with respect to perchlorate only because it is by far the dominant plume constituent and drives the cleanup timeframes for both plumes.

10.4.1 Northern Area Groundwater Modeling

The layout of designs for the active treatment components of Alternatives 3, 4, and 5 are shown in Figure 9-1. The conceptual designs for the active treatment alternatives use extraction wells, modular treatment units (MTUs) with GAC and IX to treat the contaminated water and infiltration trenches to return the water to the aquifer. The conceptual designs for Alternatives 3, 4, and 5 consist of MTUs located on Barlow Road and infiltration trenches located along Wood Road and Jefferson Road. For Alternative 5, the additional water would be returned to the aquifer through expansion of the J-2 infiltration trenches located on Wood Road. The specific method and placement of returning treated water to the aquifer will be determined during the wellfield design effort if the selected remedy involves treatment.

Groundwater modeling was used to predict the fate and transport of perchlorate in the J-2 Range Northern plume for each alternative. The existing J-2 Range northern groundwater model and the newly developed and calibrated J-2 Range northern perchlorate plume shell (January 2013) (additional details are presented in Appendix I) was used (Note: since the extent of the J-2 northern RDX plume has decreased to the point that it is fully enveloped by the larger perchlorate plume, cleanup of RDX is expected to occur simultaneously with of the perchlorate cleanup, so separate estimates of RDX remediation time frames for the J-2 northern alternatives were not developed). (Table 11-1 from the 2007 Draft J-2 Range RI/FS indicated an RDX time to 0.6 µg/L cleanup at either year 2019 or 2020, depending on the alternative.) The J-2 Range northern total perchlorate mass simulated to be in the model on 01 October 2013 at a concentration greater than 2 µg/L is 17.4 lbs and at a concentration greater than 0.35 µg/L is 21 lbs.

All model runs also incorporate other nearby operating remedial system components (i.e. J-2 Eastern Range, J-3 Range, J-1 Range, FS-12) and water supply wells that are within the model domain. The Upper Cape Water Supply wells WS-1, WS-2 and WS-3 are within the model domain and are simulated in the model at average operating conditions (i.e. 129, 297 and 148 gpm, respectively).

The fate and transport of perchlorate under stressed conditions (active remediation) were simulated for Alternatives 3, 4, and 5. Alternatives 1 and 2 have the same pumping stress (i.e., only the influence of adjacent public water supply wells and remedial systems).

Each model simulation was initialized in January 2013 and ended in September 2113. The start-up of the potential J-1 Range Northern remedial system is simulated to begin in October 2013. The extraction well locations and flow rates used in each alternative are summarized in Table 10-1. Animations 10-1 through 10-5 illustrate the future fate of the perchlorate plumes under Alternatives 1 through 5. The model-predicted mass capture was based on mass captured through the extraction wells during the estimated remediation time extending from 01 October 2013 through September 2113. The modeling results are presented in the detailed analysis of each alternative.

Predicted extraction well concentrations at the J-2 Northern range indicated that the plume shell was not able to reliably replicate measured concentrations, particularly at J2EW0001, and that the plume shell required calibration in order to be useful. The measured extraction well perchlorate concentrations at J2EW0001 were a factor of approximately 5 greater than the predicted concentrations and it was determined that the application of a multiplication factor of 5 was required to increase concentrations of the entire perchlorate plume. This increase caused the measured and predicted extraction well concentrations at J2EW0001 to be in close agreement and is a conservative approximation of the likely mass of perchlorate in the overall plume shell.

The calibrated perchlorate plume shell was simulated in the fate and transport model with Alternatives 1, 2, 3, 4, and 5 (Animations 10-1 through 10-5).

Simulation of remediation Alternatives 1 and 2 (No-Further Action and Monitored Natural Attenuation, respectively) for perchlorate indicate that if the current extraction system was deactivated on 01 October 2013, site-wide concentrations less than 15 µg/L would be achieved by 2022, site-wide concentrations less than 2 µg/L would be achieved by 2065, and site-wide concentrations less than ND would be achieved after 2113.

Simulation of remediation Alternative 3 (Current conditions) for perchlorate indicates that if the current extraction system was continued beyond 01 October 2013, site-wide concentrations less than 15 µg/L would be achieved by 2017, site-wide concentrations less than 2 µg/L would be achieved by 2029, and site-wide concentrations less than ND would be achieved after 2071.

Simulation of remediation Alternative 4 (Optimized conditions) for perchlorate indicate that if the current extraction system was optimized beyond October 1, 2013, site-wide concentrations less than 15 µg/L would be achieved by 2016, site-wide concentrations less than 2 µg/L would be achieved by 2027, and site-wide concentrations less than ND would be achieved after 2065.

Simulation of remediation Alternative 5 (10-Year Cleanup conditions) for perchlorate indicate that if the current extraction system was both optimized and amended to include two additional extraction wells beyond October 1, 2013, site-wide concentrations less than 15 µg/L would be achieved by 2016, site-wide concentrations less than 2 µg/L would be achieved by 2024, and site-wide concentrations less than ND would be achieved after 2059.

10.4.2 Alternative 1 – No Further Action

Under the no further action alternative, treatment and/or monitoring would not be conducted and the treatment system and monitoring wells associated with the northern J-2 Range plume would be abandoned. This alternative serves as a baseline for alternative comparisons.

Overall Protection of Human Health and the Environment

Alternative 1 would not prevent the migration of the plume or protect human health or the environment from the existing contamination. Although there is currently no exposure to the J-2 Range northern plume, Alternative 1 offers no monitoring or confirmation of existing Land Use Controls to ensure that future exposures do not occur. Perchlorate concentrations are predicted to decrease, through natural attenuation processes, below 15 µg/L by 2022, below 2 µg/L by approximately 2065 and background concentrations (0.35 µg/L) could be achieved after year 2113 (Table 10-1). Perchlorate concentrations above 2 µg/L may reach the Gibbs Road area under this alternative. Modeling results indicate that contaminant migration times from Gibbs Road sentry wells to WS-2 are on the order of four to nine years depending on depth. However, without monitoring or Land Use Controls, Alternative 1 would not ensure protectiveness or verify that cleanup levels were met.

Compliance with Applicable Regulations

Alternative 1 allows for continued migration of the plume. Because no further action is taken, chemical-specific regulations would be met only if, and when, contaminant concentrations decreased below the cleanup standards by natural attenuation. Based on model predictions, Alternative 1 would be compliant with chemical-specific regulations across the entire plume by approximately 2065. Because the alternative takes no action, there are no location-specific or action-specific regulations to be met.

Long-term Effectiveness and Permanence

In this Alternative, perchlorate concentrations in the plume are expected to permanently decrease to below 2 µg/L through natural attenuation processes by 2065. Because no further contribution from the source area is likely, this alternative is expected to be permanent. However, as noted above, any natural attenuation that occurred under Alternative 1 would not be monitored or verified, and thus the degree of certainty that the natural attenuation would attain cleanup goals would be low. Since Alternative 1 does not include Land Use Controls to prevent exposure, there is a potential threat to human health and the environment if the natural attenuation does not occur as predicted.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed from the site, there may be a potential for further groundwater contamination. This alternative does not include long-term groundwater monitoring to verify that any possible remaining sources will not pose a threat to groundwater. Therefore, this alternative is not expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

No further treatment would occur; therefore, no reduction in toxicity, mobility, or volume would occur through treatment. However, the toxicity and volume of the contaminated groundwater would be reduced through natural processes.

Short-term Effectiveness

There would be little to no effect on the community or natural resources from implementing Alternative 1 because no construction work would be involved other than treatment system and well abandonment. There are risks to workers from unexploded ordnance. A site-specific Health and Safety Plan (HASP) would be followed during well abandonment.

Implementability

Alternative 1 would require no technical implementation other than well abandonment, which has been done successfully many times at MMR. Administratively, this alternative is feasible.

Cost

The costs are estimated for Alternative 1 as follows:

- Capital Cost: $129,000
- O&M: $ 0
- Site closeout documentation: $ 84,000
- Total present worth: $213,000

Appendix H provides detailed calculations of the cost of Alternative 1.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.4.3 Alternative 2 – Monitored Natural Attenuation and Land Use Controls

No further extraction and treatment would occur with this alternative. This alternative would provide for long-term monitoring of the J-2 Range northern groundwater to ensure that natural attenuation was progressing towards cleanup levels and for Land Use Controls to prevent human exposure to contaminated groundwater.

On-base Land Use Controls would prevent exposure to contaminated groundwater or soil disturbance activities that might interfere with the remedy. The Land Use Controls would remain in place, and be monitored for compliance, until the concentration of COCs in the groundwater attains cleanup levels.

Monitored natural attenuation would involve periodic analysis of groundwater for perchlorate and explosives to measure the natural attenuation of the contaminated groundwater, determining when concentrations have decreased below risk-based concentrations. Additional monitoring wells may be necessary to adequately monitor the plume as it migrates downgradient of the current plume footprint into areas where there has been less monitoring well coverage. Groundwater monitoring would continue after cleanup objectives are met for two additional years to ensure that plume concentrations remain below those levels. The current active treatment system would be discontinued and infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed, if necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

Alternative 2 would not prevent the migration of the plume. Monitoring and Land Use Controls would be implemented to prevent exposure to contamination. Perchlorate concentrations are predicted to decrease, through natural attenuation processes, below 15 µg/L by 2022, 2 µg/L by approximately 2065 and background concentrations (0.35 µg/L) after year 2113 (Table 10-1). Perchlorate concentrations above 2 µg/L likely will not reach the Gibbs Road area under this alternative.

Compliance with Applicable Regulations

Alternative 2 would comply with applicable regulations. Because the plume is expected to attenuate naturally below cleanup levels, Alternative 2 would eventually be expected to meet the response action objectives, including regulatory standards for COCs.

Long-term Effectiveness and Permanence

In this Alternative, perchlorate is expected to decrease to risk-based concentrations through natural processes (dilution, dispersion, and sorption). Because no further contribution from the source area is likely, this alternative is expected to be permanent. Monitoring of the plume would continue for several years after the plume attenuates to ensure that all areas remain below remedial goals. In the meantime, the Land Use Controls would ensure that no use of the contaminated water occurs.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed from the site, there may be a potential for further groundwater contamination. This alternative includes Land Use Controls, which would minimize future exposure. It also includes long-term groundwater monitoring to verify that any possible remaining sources will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

No further treatment would occur; therefore, no reduction in toxicity, mobility, or volume would occur through treatment. However, the toxicity and volume of the contaminated groundwater would be reduced through natural processes.

Short-term Effectiveness

There would be little effect on the community because all short-term activity is on-post. There would be less effect on the workers because activities would be limited to monitoring well construction, sampling and well abandonment. A HASP would be followed during construction and long-term groundwater monitoring. To date, health and safety precautions for unexploded ordnance clearance, groundwater sampling, and drilling have been adequate to protect workers.

To the extent feasible, previously disturbed areas would be utilized for the installation of wells to minimize impact on cultural and natural resources. However, some disturbance of natural resources may be necessary to complete this alternative.

Implementability

Groundwater monitoring associated with the J-2 Range northern plume would continue, subject to periodic optimization, using the same sampling and analytical protocols currently in use. Administratively, this alternative is feasible. There are no implementability concerns anticipated with obtaining access for additional monitoring well installation because the locations would be on-post. There is a potential administrative implementability concern for monitoring well sampling and installation after the military's lease expires, because it is unknown what the administrative requirements will be necessary to perform those tasks.

Cost

The present worth costs were estimated for Alternative 2 as follows:

- Capital Cost: $ 377,000
- O&M: $2,358,000
- Site closeout documentation: $ 48,000
- Total present worth: $2,783,000

Appendix H provides detailed calculations of the cost of Alternative 2.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.4.4 Alternative 3 – Focused Extraction with 3 Wells, Monitored Natural Attenuation and Land Use Controls (Continued Operation of Current System)

Alternative 3 would provide for operation of the J-2 Range northern groundwater plume rapid response action (RRA) extraction treatment injection (ETI) system (Figure 9-1). The J-2 Range northern groundwater plume RRA ETI system consists of wells J2EW0001 pumping at 75 gpm, J2EW0002 pumping at 175 gpm, and J2EW0003 pumping at 125 gpm, for a combined pumping rate of 375 gpm and four infiltration trenches located to the northeast, southeast, southwest, and northwest of the northern J-2 plume. Active treatment of the plume removes perchlorate and RDX from the extracted groundwater and returns the treated water to the aquifer. This alternative includes the option of modifying the system to optimize the system performance.

This alternative would include for chemical and hydraulic monitoring of the plume and treatment system as long as active remediation continues, and chemical monitoring of the aquifer after the system is turned off, to ensure that perchlorate and RDX concentrations have decreased below risk-based concentrations. Land Use Controls would minimize potential future exposure. Groundwater monitoring would continue for two years after risk-based concentrations were achieved to ensure that concentrations remain below those levels. The monitoring wells and other infrastructure would be abandoned when no longer needed. A residual risk assessment would be performed, if necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

The groundwater model indicates that perchlorate concentrations are expected to decrease below 15 µg/L by 2017, 2 µg/L by approximately 2029 and background concentrations (0.35 µg/L) could be achieved by 2071 (Table 10-1). Perchlorate concentrations above 2 µg/L likely will not reach the Gibbs Road area under this alternative.

Compliance with Applicable Regulations

Alternative 3 would comply with applicable regulations.

Long-term Effectiveness and Permanence

Both active treatment and natural attenuation components of the alternative would be permanent. Groundwater extraction and treatment would permanently remove some of the perchlorate and RDX from groundwater. The remaining contamination would continue to degrade due to natural attenuation processes, some of which would also be irreversible.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

Extraction and treatment of groundwater would reduce the toxicity, mobility and volume of perchlorate and RDX. The total mass of perchlorate in the J-2 northern plume (greater than 2 µg/L) as simulated in the model was 17.4 pounds. The total perchlorate mass above detection limits (0.35 µg/L) was 21.0 pounds. Model-predicted mass capture for Alternative 3 is approximately 13.9 pounds of perchlorate.

Short-term Effectiveness

There would be little effect on the community because most activity is on-post. There would be some effect on the workers during monitoring, well construction, sampling and decommissioning.

A site-specific Health and Safety Plan would be followed during any treatment system installation and system operation and monitoring where engineering controls and Personal Protective Equipment would be used as necessary to limit potential exposure to COCs. To date, health and safety precautions for unexploded ordnance clearance, construction activities, groundwater sampling and drilling have been adequate to protect workers.

To the extent feasible, previously disturbed areas would be utilized for the installation of wells, the infiltration trench, subsurface piping, power lines, and the MTU to minimize impact on cultural and natural resources. However, some temporary disturbance to the vegetation would be necessary during installation of the treatment system.

Implementability

Administratively, this alternative would be feasible. IX has been shown to be effective in treating perchlorate. GAC has been shown to be effective in treating RDX. The treatment system would require regular maintenance and monitoring. Experience at other sites suggests that the components would be reliable. Maintenance of facilities downrange of a small arms firing range would require detailed coordination to ensure safe operation. The Massachusetts Army National Guard's Revised Limited Authorization for Lead Ammunition Training (AO2, Appendix C) at Tango, Juliet, and Kilo Ranges, and as noted in an 08 January 2012 EPA letter concerning training with copper ammunition, is conditioned on such coordination and specifically provides that investigation and cleanup take priority in the event of a conflict.

Cost

The present worth costs were estimated for Alternative 3 as follows:

- Capital Cost: $ 547,000
- O&M: $5,205,000
- Site closeout documentation: $ 73,000
- Total present worth: $5,825,000

Appendix H provides detailed calculations of the cost of Alternative 3.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.4.5 Alternative 4 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (Optimization of Current System)

Alternative 4 would provide for pumping and treatment of the J-2 Range northern groundwater plume, monitoring, and maintaining Land Use Controls. The conceptual design for Alternative 4 involves optimizing the pumping rates within the existing J-2 Range northern groundwater ETI system. The conceptual design includes a flow rate at J2EW0001 of 150 gpm, a flow rate at J2EW0002 of 100 gpm, and a flow rate at J2EW0003 of 125 gpm, for a total combined pumping rate of 375 gpm (Figure 9-1).

This alternative would include chemical and hydraulic monitoring of the plume and treatment system as long as active remediation continues and chemical monitoring of the aquifer after the system is turned off, to ensure that perchlorate and RDX concentrations have decreased below risk-based concentrations. Land Use Controls would minimize potential future exposure. Groundwater monitoring would continue for two years after risk-based concentrations are achieved to ensure that plume concentrations remain below those levels. The monitoring wells and other subsurface infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed as necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

The groundwater model indicates that perchlorate concentrations are expected to decrease below 15 µg/L by 2016, 2 µg/L by approximately 2027 and background concentrations

(0.35 µg/L) could be achieved by approximately 2065. (Table 10-1). Perchlorate concentrations above 2 µg/L likely will not reach the Gibbs Road area under this alternative.

Compliance with Applicable Regulations

Alternative 4 would comply with applicable regulations.

Long-term Effectiveness and Permanence

Both active treatment and natural attenuation components of the alternative would be permanent. Groundwater extraction and treatment would permanently remove some of the perchlorate and RDX from groundwater. The remaining contamination would continue to degrade due to natural attenuation processes, which would also be irreversible.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

Extraction and treatment of groundwater would reduce the toxicity, mobility and volume of perchlorate and RDX. The total mass of perchlorate in the J-2 northern plume (greater than 2 µg/L) as simulated in the model was 17.4 pounds. The total perchlorate mass above detection limits was 21.0 pounds. Model-predicted mass capture for Alternative 4 is approximately 13.2 pounds of perchlorate.

Short-term Effectiveness

There would be little effect on the community because most activity is on-post. There would be some effect on the workers during monitoring, well construction, sampling and decommissioning.

A site specific Health and Safety Plan would be followed during construction activities and system operation and monitoring where engineering controls and Personal Protective Equipment would be used as necessary. To date, health and safety precautions for unexploded ordnance clearance, groundwater sampling and drilling have been adequate to protect workers. To the extent feasible, previously disturbed areas would be utilized for the installation of wells, infiltration trenches, subsurface piping, power lines, and the MTUs to minimize impact on cultural and natural resources. However, some temporary disturbance to the vegetation would be necessary during installation of the treatment system.

Implementability

Administratively, this alternative would be feasible. IX has been shown to be effective in treating perchlorate. GAC has been shown to be effective in treating RDX. The treatment system would require regular maintenance and monitoring. Experience at other sites suggests that the components would be reliable.

The Massachusetts Army National Guard's Revised Limited Authorization for Lead Ammunition Training (AO2, Appendix C) at Tango, Juliet, and Kilo Ranges, is conditioned on such coordination and specifically provides that investigation and cleanup take priority in the event of a conflict.

Cost

The present worth costs were estimated for Alternative 4 as follows:

- Capital Cost: $ 549,000
- O&M: $4,723,000
- Site closeout documentation: $ 74,000
- Total present worth: $5,346,000

Appendix H provides detailed calculations of the cost of Alternative 4.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.4.6 Alternative 5 – Focused Extraction with Five Wells, Monitored Natural Attenuation and Land Use Controls

Alternative 5 would provide for pumping and treatment of the J-2 Range northern groundwater plume, monitoring, and maintaining Land Use Controls. The conceptual design for Alternative 5 includes a flow rate at J2EW0001 of 150 gpm, a flow rate at J2EW0002 of 200 gpm, a flow rate of 125 gpm at J2EW0003, and two new extraction wells (one shallow at 100 gpm and one deep at 50 gpm) would be installed for a total combined pumping rate of 625 gpm. (Figure 9-1).

This alternative would include chemical and hydraulic monitoring of the plume and treatment system as long as active remediation continues and chemical monitoring of the aquifer after the system is turned off, to ensure that perchlorate and RDX concentrations have decreased below risk-based concentrations. Land Use Controls would minimize potential future exposure. Groundwater monitoring would continue for two years after risk-based concentrations are achieved to ensure that plume concentrations remain below those levels. The monitoring wells and other subsurface infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed as necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

The groundwater model indicates that perchlorate concentrations are expected to decrease below 15 µg/L by 2016, 2 µg/L by approximately 2024 and background concentrations (0.35 µg/L) could be achieved by approximately 2059 (Table 10-1). Perchlorate concentrations above 2 µg/L likely will not reach the Gibbs Road area under this alternative.

Compliance with Applicable Regulations

Alternative 4 would comply with applicable regulations.

Long-term Effectiveness and Permanence

Both active treatment and natural attenuation components of the alternative would be permanent. Groundwater extraction and treatment would permanently remove some of the perchlorate and RDX from groundwater. The remaining contamination would continue to degrade due to natural attenuation processes, which would also be irreversible.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

Extraction and treatment of groundwater would reduce the toxicity, mobility and volume of perchlorate and RDX. The total mass of perchlorate in the J-2 northern plume (greater than 2 µg/L) as simulated in the model was 17.4 pounds. The total perchlorate mass above detection limits was 21.0 pounds. Model-predicted mass capture for Alternative 5 is approximately 11.6 pounds of perchlorate.

Short-term Effectiveness

There would be little effect on the community because most activity is on-post. There would be some effect on the workers during monitoring, well construction, sampling and decommissioning.

A site specific Health and Safety Plan would be followed during construction activities and system operation and monitoring where engineering controls and Personal Protective Equipment would be used as necessary. To date, health and safety precautions for unexploded ordnance clearance, groundwater sampling and drilling have been adequate to protect workers. To the extent feasible, previously disturbed areas would be utilized for the installation of wells, infiltration trenches, subsurface piping, power lines, and the MTUs to minimize impact on cultural and natural resources. However, some temporary disturbance to the vegetation would be necessary during installation of the treatment system.

Implementability

Administratively, this alternative would be feasible. IX has been shown to be effective in treating perchlorate. GAC has been shown to be effective in treating RDX. The treatment system would require regular maintenance and monitoring. Experience at other sites suggests that the components would be reliable.

The Massachusetts Army National Guard’s Revised Limited Authorization for Lead Ammunition Training (AO2, Appendix C) at Tango, Juliet, and Kilo Ranges, is conditioned on such coordination and specifically provides that investigation and cleanup take priority in the event of a conflict.

Cost

The present worth costs were estimated for Alternative 5 as follows:

- Capital Cost: $ 3,745,000
- O&M: $ 6,869,000
- Site closeout documentation: $ 76,000
- Total present worth: $10,690,000

Appendix H provides detailed calculations of the cost of Alternative 5.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.5 Eastern Area Feasibility Study

The following sections provide the J-2 Range Eastern groundwater modeling activities and results, and a detailed description and analysis of the remedial alternatives. Each alternative description includes assumptions made for planning and cost-estimating purposes.

10.5.1 Eastern Area Groundwater Modeling

The layout of designs for the active treatment components of Alternatives 3, 4, and 5 are shown in Figure 9-2. The conceptual designs for the active treatment alternatives use extraction wells, modular treatment units (MTUs) with GAC and IX to treat the contaminated water and infiltration trenches to return the water to the aquifer. The conceptual designs for Alternatives 3, 4, and 5 consist of MTUs located on Greenway Road and infiltration trenches located along Greenway Road and Wood Road, outside of the plume. For Alternative 5, the conceptual design consists of piping the contaminated water to MTUs located adjacent to the J-2 Range Eastern MTUs on Greenway Road. The water would be returned to the aquifer through expansion of the J-2 infiltration trenches located on Wood Road. The specific method and placement of returning treated water to the aquifer will be determined during the wellfield design effort if the selected remedy involves treatment.

Groundwater modeling was used to predict the fate and transport of perchlorate and RDX in the J-2 Range Eastern plume for each alternative. The J-2 Range Eastern groundwater model and the newly developed J-2 Range Eastern perchlorate and RDX plume shells (October 2012) (Appendix I) were used. The J-2 Range Eastern total perchlorate mass simulated to be in the model on 01 October 2013 at a concentration greater than 2 µg/L is 16.8 lbs and at a concentration of greater than 0.35 µg/L is 20.6 lbs.

All model runs also incorporate other nearby operating remedial system components (i.e. J-2 Eastern Range, J-3 Range, J-1 Range, FS-12) and water supply wells that are within the model domain. The Upper Cape Water Supply wells WS-1, WS-2 and WS-3 are within the model domain and are simulated in the model at average operating conditions (i.e. 129, 297 and 148 gpm, respectively). Additionally, unlike the J-2 Range Northern simulations, contaminant was not mapped to low permeability portions of the aquifer and cleanup times do not consider contaminant that may have migrated into these low permeability layers during the simulations.

The fate and transport of perchlorate and RDX under stressed conditions (active remediation) were simulated for Alternatives 3, 4, and 5. Alternatives 1 and 2 have the same pumping stress (i.e. only the influence of adjacent public water supply wells and remedial systems).

Each model simulation was initialized in January 2013 and ended in September 2113. The start-up of the potential J-1 Range eastern remedial system is simulated to begin in October 2013. The extraction well locations and flow rates used in each alternative are summarized in Table 10 -1. Animations 10-6 through 10-10 illustrate the future fate of the perchlorate plumes under Alternatives 1 through 5 and Animations 10-11 through 10-16 illustrate the future fate of the RDX plumes under the same set of alternatives. The model-predicted mass capture was based on mass captured through the extraction wells during the estimated remediation time extending from 01 October 2013 through September 2113. The modeling results are presented in the detailed analysis of each alternative.

Simulation of remediation Alternatives 1 and 2 (No Further Action and Monitored Natural Attenuation, respectively) for perchlorate indicate that if the current extraction system was deactivated on October 1, 2013, site-wide concentrations less than 15 µg/L would be achieved by 2026, site-wide concentrations less than 2 µg/L would be achieved by 2104.

Simulation of remediation Alternative 3 (Current conditions) for perchlorate indicates that if the current extraction system was continued beyond October 1, 2013, site-wide concentrations less than 15 µg/L would be achieved by 2018, site-wide concentrations less than 2 µg/L would be achieved by 2027, and site-wide concentrations less than ND would be achieved after 2058.

Simulation of remediation Alternative 4 (Optimized conditions) for perchlorate indicates that if the current extraction system was optimized beyond October 1, 2013, site-wide concentrations less than 15 µg/L would be achieved by 2018, site-wide concentrations less than 2 µg/L would be achieved by 2027, and site-wide concentrations less than ND would be achieved after 2066.

Simulation of remediation Alternative 5 (10-Year Cleanup conditions) for perchlorate indicate that if the current extraction system was both optimized and amended to include two additional extraction wells beyond 01 October 2013, site-wide concentrations less than 15 µg/L would not be achieved until 2016, site-wide concentrations less than 2 µg/L would not be achieved until 2022, and site-wide concentrations less than ND would not be achieved until after 2035.

10.5.2 Alternative 1 – No Further Action

Under the no further action alternative, treatment and/or monitoring would not be conducted and the monitoring wells associated with the J-2 Range eastern plume treatment system and long-term chemical monitoring would be abandoned. This alternative serves as a baseline for alternative comparisons.

<u>Overall Protection of Human Health and the Environment</u>

Alternative 1 would not prevent the migration of the plume or protect human health or the environment from the existing contamination. Although residences in the area are believed to be on town water, Alternative 1 offers no monitoring or confirmation of existing Land Use Controls to ensure that future exposures do not occur. Perchlorate concentrations are predicted to decrease, through natural attenuation processes, below 15 µg/L by approximately 2026, 2 µg/L by approximately 2104 and background concentrations (0.35 µg/L) would be achieved after year

2113. RDX concentrations are predicted to decrease, through natural attenuation processes, below the 10^{-5} risk–based level of 6 µg/L by 2014, HA of 2 µg/L by approximately 2028, below the 10^{-6} risk-based level of 0.6 µg/L by 2055, and background concentrations (0.25 µg/L) could be achieved after year 2113 (Table 10-1). Perchlorate would likely migrate well beyond Gibbs Road at concentrations above 2 µg/L under this alternative but would remain within the base boundary. RDX concentrations above 0.6 µg/L would likely migrate just beyond MW-436 under this alternative. However, without monitoring or Land Use Controls, Alternative 1 would not ensure protectiveness or verify that cleanup levels were met.

Compliance with Applicable Regulations

Alternative 1 allows for continued migration of the plume. Because no further action is taken, chemical-specific regulations would be met only if and when contaminant concentrations decreased below the cleanup standards by natural attenuation. Based on model predictions, Alternative 1 would be compliant with chemical-specific regulations across the entire plume by approximately 2075. Because the alternative takes no action, there are no location-specific or action-specific regulations to be met.

Long-term Effectiveness and Permanence

In this alternative, perchlorate and RDX concentrations in the plume are expected to permanently decrease to below 2 µg//L and 0.6 µg//L through natural attenuation processes by 2075 and 2061 respectively. Because no further contribution from the source area is likely, this alternative is expected to be permanent. However, as noted above, any natural attenuation that occurred under Alternative 1 would not be monitored or verified, and thus the degree of certainty that the natural attenuation would attain cleanup goals would be low. Since Alternative 1 does not include Land Use Controls to prevent exposure, there is a potential threat to human health and the environment if the natural attenuation does not occur as predicted.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative does not include long-term groundwater monitoring to verify that any possible remaining sources will not pose a threat to groundwater. Therefore, this alternative is not expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

No further treatment would occur; therefore, no reduction in toxicity, mobility, or volume would occur through treatment. However, the toxicity and volume of the contaminated groundwater would be reduced through natural processes.

Short-term Effectiveness

There would be little to no effect on the community or natural resources from implementing Alternative 1 because no construction work would be involved other than well abandonment. There are risks to workers from unexploded ordnance. A site-specific Health and Safety Plan (HASP) would be followed during well abandonment.

Implementability

Alternative 1 would require no technical implementation other than well abandonment, which has been done successfully many times at MMR. Administratively, this alternative is feasible.

Cost

The costs are estimated for Alternative 1 as follows:

- Capital Cost: $161,000
- O&M: $ 0
- Site closeout documentation: $ 84,000
- Total present worth: $245,000

Appendix H provides detailed calculations of the cost of Alternative 1.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.5.3 Alternative 2 – Monitored Natural Attenuation with Land Use Controls

No further extraction and treatment would occur with this alternative. This alternative would provide for long-term monitoring of the J-2 Range eastern groundwater to ensure that natural attenuation was progressing towards cleanup levels and for Land Use Controls to prevent human exposure to contaminated groundwater.

Land Use Controls would prevent exposure to contaminated groundwater or soil disturbance activities that might interfere with the remedy. The Land Use Controls would remain in place and be monitored for compliance until the concentration of COCs in the groundwater attains cleanup levels.

The monitored natural attenuation would involve periodic analysis of groundwater for perchlorate and explosives to measure the natural attenuation of the contaminated groundwater, determining when concentrations have decreased below risk-based concentrations. Groundwater monitoring would continue after cleanup objectives are met for two additional years to ensure that plume concentrations remain below those levels. The current active treatment system would be discontinued and infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed, if necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

Alternative 2 would not prevent the migration of the plume. Monitoring and Land Use Controls would be implemented to prevent exposure to contamination. Perchlorate concentrations are predicted to decrease, through natural attenuation processes, below 15 µg/L by 2026, 2 µg/L by approximately 2104 and background concentrations (0.35 µg/L) after year 2113. RDX concentrations are predicted to decrease, through natural attenuation processes, below the 10^{-5} risk-based level of 6 µg/L by approximately 2014, the HA of 2 µg/L by approximately 2028, the 10^{-6} risk-based level of 0.6 µg/L by 2055, and background concentrations (0.25 µg/L) after year 2113 (Table 10-1).

Compliance with Applicable Regulations

Alternative 2 would comply with applicable regulations. Because the plume is expected to naturally attenuate below cleanup levels, Alternative 2 would eventually be expected to meet the response action objectives, including regulatory standards for COCs.

Long-term Effectiveness and Permanence

In this alternative, perchlorate and RDX concentrations would decrease to risk-based concentrations through natural processes (dilution, dispersion, and sorption). Because no further contribution from the source area is likely, this alternative is expected to be permanent. Monitoring of the plume would continue for several years after the plume attenuates to ensure that all areas remain below remedial goals. In the meantime, the Land Use Controls would ensure that no use of the contaminated water occurs.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

No further treatment would occur; therefore, no reduction in toxicity, mobility, or volume would occur through treatment. However, the toxicity and volume of the contaminated groundwater would be reduced through natural processes.

Short-term Effectiveness

There would be little effect on the community because all short-term activity is on-post. There would be less effect on the workers because activities would be limited to monitoring well construction, sampling and well abandonment. A HASP would be followed during construction and long-term groundwater monitoring. To date, health and safety precautions for unexploded ordnance clearance, groundwater sampling, and drilling have been adequate to protect workers.

To the extent feasible, previously disturbed areas would be utilized for the installation of wells to minimize impact on cultural and natural resources. However, some disturbance of natural resources may be necessary to complete this alternative.

Implementability

Groundwater monitoring associated with the J-2 Range eastern plume would continue, subject to periodic optimization, using the same sampling and analytical protocols currently in use. Administratively, this alternative is feasible. There are no implementability concerns anticipated with obtaining access for any additional monitoring well installation because the locations would be on-post. There is a potential administrative implementability concern for monitoring well sampling and installation after the military's lease expires, because it is unknown what the administrative requirements will be necessary to perform those tasks.

Cost

The present worth costs were estimated for Alternative 2 as follows:

- Capital Cost: $ 442,000
- O&M: $2,758,000
- Site closeout documentation: $ 30,000
- Total present worth: $3,230,000

Appendix H provides detailed calculations of the cost of Alternative 2.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.5.4 Alternative 3 –Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (Continued Operation of Current System)

Alternative 3 would provide for operation of the J-2 Range eastern groundwater plume rapid response action (RRA) ETI system (Figure 9-2). The J-2 Range eastern groundwater plume RRA ETI system consists of wells J2EW0004 pumping at 90 gpm, J2EWW0005 pumping at 210 gpm, and J2EW0006 pumping at 125 gpm for a combined rate of 425 gpm, and three infiltration trenches located to the northeast, southeast, and southwest of the eastern J-2 plume. Active treatment of the plume removes perchlorate and RDX from the extracted groundwater and returns the treated water to the aquifer. This alternative includes the option of modifying the system to optimize the system performance.

Land Use Controls would prevent exposure to contaminated groundwater or soil disturbance activities that might interfere with the remedy. The Land Use Controls would remain in place and be monitored for compliance until the concentrations of COCs in the groundwater attains cleanup levels.

This alternative would include for chemical and hydraulic monitoring of the plume and treatment system as long as active remediation continues, and chemical monitoring of the aquifer after the system is turned off, to ensure that perchlorate and RDX concentrations have decreased below risk-based concentrations. Groundwater monitoring would continue for two years after risk-based concentrations were achieved to ensure that concentrations remain below those concentrations. The monitoring wells and other infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed, if necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

The groundwater model indicates that perchlorate concentrations are expected to decrease below 15 µg/L by 2018, 2 µg/L by approximately 2027 and background concentrations (0.35 µg/L) could be achieved by 2058. Perchlorate concentrations above 2 µg/L likely would not migrate significantly beyond the Wood Road area under this alternative. RDX concentrations are expected to decrease below the 10^{-5} risk-based level of 6 µg/L by approximately 2014, the HA of 2 µg/L by approximately 2018, below the 10^{-6} risk-based level of 0.6 µg/L by 2023, and background concentrations (0.25 µg/L) could be achieved by 2031 (Table 10-1). RDX concentrations above 0.6 µg/L would likely migrate to the west of but not beyond MW-436 under this alternative.

Compliance with Applicable Regulations

Alternative 3 would comply with applicable regulations.

Long-term Effectiveness and Permanence

Both active treatment and natural attenuation components of the alternative would be permanent. Groundwater extraction and treatment would permanently remove some of the perchlorate and RDX from groundwater. The remaining contamination would continue to degrade due to natural attenuation processes, which would also be irreversible.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

Extraction and treatment of groundwater would reduce the toxicity, mobility and volume of perchlorate and RDX. The total mass of perchlorate in the J-2 eastern plume (greater than 2 µg/L) as simulated in the model was 16.8 pounds. The total perchlorate mass above detection limits was 20.6 pounds. The total mass of RDX in the eastern plume (greater than 2 µg/L) as simulated in the model was 1.8 pounds and 2.7 pounds greater than the detection limit. Model-predicted mass capture for Alternative 3 is approximately 13 pounds of perchlorate and 2.9 pounds of RDX.

Short-term Effectiveness

There would be little effect on the community because most activity is on-post. There would be some effect on the workers during monitoring, well construction, sampling and decommissioning.

A site-specific Health and Safety Plan would be followed during construction activities and system operation and monitoring where engineering controls and Personal Protective Equipment would be used as necessary to limit potential exposure to COCs. To date, health and safety precautions for unexploded ordnance clearance, construction activities, groundwater sampling and drilling have been adequate to protect workers.

Implementability

Administratively, this alternative would be feasible. IX has been shown to be effective in treating perchlorate. GAC has been shown to be effective in treating RDX. The treatment system would require regular maintenance and monitoring. Experience at other sites suggests that the components would be reliable.

Cost

The present worth costs were estimated for Alternative 3 as follows:

- Capital Cost: $ 729,000
- O&M: $4,723,000
- Site closeout documentation: $ 74,000
- Total present worth: $5,526,000

Appendix H provides detailed calculations of the cost of Alternative 3.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.5.5 Alternative 4 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls (Optimization of Current System)

Alternative 4 would provide for pumping and treatment of the J-2 Range eastern groundwater plume, monitoring, and maintaining Land Use Controls. The conceptual design for Alternative 4 involves the optimization of the pumping rates of the existing J-2 Range eastern groundwater ETI system. The conceptual design involves a flow rate at J2EW0004 of 120 gpm, a flow rate at J2EW0005 of 250 gpm, and a flow rate at J2EW0006 of 125 gpm for a total combined pumping rate of 495 gpm (Figure 9-2). The current J-2 Range eastern treatment facilities would need to be expanded to treat the additional flow and the effluent would be returned to the aquifer through expanding the existing infiltration trenches.

Land Use Controls would prevent exposure to contaminated groundwater or soil disturbance activities that might interfere with the remedy. The Land Use Controls would remain in place and be monitored for compliance until the concentrations of COCs in the groundwater attain cleanup levels.

This alternative would include chemical and hydraulic monitoring of the plume and treatment system as long as active remediation continues, and chemical monitoring of the aquifer after the system is turned off, to ensure that perchlorate and RDX concentrations have decreased below risk-based concentrations. Groundwater monitoring would continue for two years after risk-based concentrations were achieved to ensure that concentrations remain below those concentrations. The monitoring wells and other infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed, if necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

The groundwater model indicates that perchlorate concentrations are expected to decrease below 15 µg/L by 2018, 2 µg/L by approximately 2027 and background concentrations (0.35 µg/L) could be achieved by approximately 2058. Perchlorate concentrations above 2 µg/L likely would not migrate significantly beyond the Wood Road area under this alternative. RDX concentrations are expected to decrease below the 10^{-5} risk-based level of 6 µg/L by approximately 2014, the HA of 2 µg/L by approximately 2017, below the 10^{-6} risk-based level of 0.6 µg/L by 2022, and background concentrations (0.25 µg/L) could be achieved by 2030 (Table 10-1). RDX concentrations above 0.6 µg/L would likely migrate to the west of but not beyond MW-436 under this alternative.

<u>Compliance with Applicable Regulations</u>

Alternative 4 would comply with applicable regulations.

<u>Long-term Effectiveness and Permanence</u>

Both active treatment and natural attenuation components of the alternative would be permanent. Groundwater extraction and treatment would permanently remove some of the perchlorate and RDX from groundwater. The remaining contamination would continue to degrade due to natural attenuation processes, which would also be irreversible.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

<u>Reduction of Toxicity, Mobility, or Volume through Treatment</u>

Extraction and treatment of groundwater would reduce the toxicity, mobility and volume of perchlorate and RDX. The total mass of perchlorate in the J-2 eastern plume (greater than 2 µg/L) as simulated in the model was 16.8 pounds. The total perchlorate mass above detection limits (0.35 µg/L) was 20.6 pounds. The total mass of RDX in the eastern plume as simulated in the model was 1.8 pounds greater than 2 µg/L and 2.7 pounds greater than the detection limit. Model-predicted mass capture for Alternative 4 is approximately 13.5 pounds of perchlorate and 2.8 pounds of RDX.

<u>Short-term Effectiveness</u>

There would be little effect on the community because most activity is on-post. There would be some effect on the workers during monitoring, well construction, sampling and decommissioning.

A site specific Health and Safety Plan would be followed during construction activities and system operation and monitoring where engineering controls and Personal Protective Equipment would be used as necessary. To date, health and safety precautions for unexploded ordnance clearance, construction activities, groundwater sampling and drilling have been adequate to protect workers.

To the extent feasible, previously disturbed areas would be utilized for the installation of wells and subsurface piping to minimize impact on cultural and natural resources. However, some temporary disturbance of natural resources would be necessary.

<u>Implementability</u>

Administratively, this alternative would be feasible. IX has been shown to be effective in treating perchlorate. GAC has been shown to be effective in treating RDX. The treatment system would require regular maintenance and monitoring. Experience at other sites suggests that the components would be reliable.

Cost

The present worth costs were estimated for Alternative 4 as follows:

- Capital Cost: $ 729,000
- O&M: $5,177,000
- Site closeout documentation: $ 74,000
- Total present worth: $5,980,000

Appendix H provides detailed calculations of the cost of Alternative 4.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

10.5.6 Alternative 5 – Focused Extraction with Five Wells, Monitored Natural Attenuation and Land Use Controls

Alternative 5 would provide for pumping and treatment of the J-2 Range eastern groundwater plume, monitoring, and maintaining Land Use Controls. The conceptual design for Alternative 5 involves the optimization of the pumping rates of the existing J-2 Range eastern groundwater ETI system and the installation of two new extraction wells. The conceptual design involves a flow rate at J2EW0004 of 150 gpm, a flow rate at J2EW0005 of 250 gpm, a flow rate at J2EW0006 of 125 gpm, and installation of two new extraction wells (upgradient of J2EW0005) operating at a flow rate of 175 gpm and 150 gpm for a total combined pumping rate of 850 gpm (Figure 9-2). The current J-2 Range eastern treatment facilities would need to be expanded to treat the additional flow and the effluent would be returned to the aquifer through expanding the existing infiltration trenches.

Land Use Controls would prevent exposure to contaminated groundwater or soil disturbance activities that might interfere with the remedy. The Land Use Controls would remain in place and be monitored for compliance until the concentrations of COCs in the groundwater attain cleanup levels.

This alternative would include chemical and hydraulic monitoring of the plume and treatment system as long as active remediation continues, and chemical monitoring of the aquifer after the system is turned off, to ensure that perchlorate and RDX concentrations have decreased below risk-based concentrations. Groundwater monitoring would continue for two years after risk-based concentrations were achieved to ensure that concentrations remain below those concentrations. The monitoring wells and other infrastructure would be abandoned at the end of the project. A residual risk assessment would be performed, if necessary, and may include additional data collection and analysis.

Overall Protection of Human Health and the Environment

The groundwater model indicates that perchlorate concentrations are expected to decrease below 15 µg/L by 2016, 2 µg/L by approximately 2022 and background concentrations (0.35 µg/L) could be achieved by approximately 2035. Perchlorate concentrations above 2 µg/L likely would not migrate beyond the Wood Road area under this alternative. RDX concentrations are expected to decrease below the 10^{-5} risk-based level of 6 µg/L by approximately 2014, the HA of 2 µg/L by approximately 2016, below the 10^{-6} risk-based level of 0.6 µg/L by 2021, and background concentrations (0.25 µg/L) could be achieved by 2026 (Table 10-1). RDX concentrations above 0.6 µg/L would likely migrate to the west of but not beyond MW-436 under this alternative.

Compliance with Applicable Regulations

Alternative 5 would comply with applicable regulations.

Long-term Effectiveness and Permanence

Both active treatment and natural attenuation components of the alternative would be permanent. Groundwater extraction and treatment would permanently remove some of the perchlorate and RDX from groundwater. The remaining contamination would continue to degrade due to natural attenuation processes, which would also be irreversible.

The source response actions already taken addressed the majority of source material, including unexploded ordnance that may be acting as a current source. However, because not all potential source material has been removed, there may be a potential for further groundwater contamination. This alternative includes long-term groundwater monitoring to verify that any possible remaining source will not pose a threat to groundwater. Therefore, this alternative is expected to be effective over the long-term.

Reduction of Toxicity, Mobility, or Volume through Treatment

Extraction and treatment of groundwater would reduce the toxicity, mobility and volume of perchlorate and RDX. The total mass of perchlorate in the J-2 eastern plume (greater than 2 µg/L) as simulated in the model was 16.8 pounds. The total perchlorate mass above detection limits was 20.6 pounds. The total mass of RDX in the eastern plume as simulated in the model was 1.8 pounds greater than 2 µg/L and 2.7 pounds greater than the detection limit. Model-predicted mass capture for Alternative 5 is approximately 14.2 pounds of perchlorate and 3.1 pounds of RDX.

Short-term Effectiveness

There would be little effect on the community because most activity is on-post. There would be some effect on the workers during monitoring, well construction, sampling and decommissioning.

A site specific Health and Safety Plan would be followed during construction activities and system operation and monitoring where engineering controls and Personal Protective Equipment would be used as necessary. To date, health and safety precautions for unexploded ordnance clearance, construction activities, groundwater sampling and drilling have been adequate to protect workers.

To the extent feasible, previously disturbed areas would be utilized for the installation of wells and subsurface piping to minimize impact on cultural and natural resources. However, some temporary disturbance of natural resources would be necessary.

Implementability

Administratively, this alternative would be feasible. IX has been shown to be effective in treating perchlorate. GAC has been shown to be effective in treating RDX. The treatment system would require regular maintenance and monitoring. Experience at other sites suggests that the components would be reliable.

Cost

The present worth costs were estimated for Alternative 5 as follows:

- Capital Cost: $3,748,000
- O&M: $5,660,000
- Site closeout documentation: $ 77,000
- Total present worth: $9,485,000

Appendix H provides detailed calculations of the cost of Alternative 5.

State Acceptance

This criterion will be evaluated throughout the development, screening and analysis of alternatives based on comments and input received from MassDEP.

Community Acceptance

This criterion will be evaluated throughout the development, screening, and analysis of alternatives based on comments and input received from the MMRCT and the public.

11.0 COMPARISON OF ALTERNATIVES

A comparative analysis was conducted to evaluate the relative performance of each alternative in relation to each criterion. The presentation of the comparative analysis refers to each alternative by its number.

11.1 Northern Area

For reference, a brief description of each alternative follows:

Alternative 1 – No Further Action. Monitoring wells would be abandoned and site-closeout documentation would be completed.

Alternative 2 – Monitored Natural Attenuation with Land Use Controls. Alternative 2 includes long-term groundwater monitoring until COC concentrations attain cleanup levels and Land Use Controls.

Alternative 3 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls. Alternative 3 includes the continued operation of the current J-2 Range northern groundwater plume ETI system. The J-2 Range northern groundwater plume ETI system consists of three axial extraction wells pumping at a combined rate of 375 gpm and four infiltration trenches located to the northeast, southeast, southwest, and northwest of the northern J-2 plume.

Alternative 4 – Focused Extraction with Five Wells, Monitored Natural Attenuation and Land Use Controls. Alternative 4 includes the continued operation of the current J-2 Range northern groundwater plume ETI system with optimization of the pumping rates within the existing J-2 extraction wells, wells for a total combined pumping rate of 375 gpm.

Alternative 5 – Focused Extraction with Five Wells, Monitored Natural Attenuation and Land Use Controls. Alternative 5 includes the continued operation of the current J-2 Range northern groundwater plume ETI system with optimization of the pumping rates and the installation of two new extraction wells (one shallow and one deep) for a total combined pumping rate of 625 gpm.

The strengths and weaknesses of each alternative are presented in a narrative that addresses each criterion.

11.1.1 Overall Protection of Human Health and the Environment

Alternatives 2 through 5 would be protective of human health and the environment. Alternative 1, however, offers no monitoring or confirmation of existing Land Use Controls to ensure that future exposures do not occur. Alternative 2 adds provisions for plume monitoring and Land Use Controls to help prevent future exposure to contaminated groundwater. Alternatives 3, 4 and 5 add extraction and treatment components and achieve risk-based concentrations earlier than Alternatives 1 and 2.

Alternative	Perchlorate Cleanup Times	
	15 µg/L	2 µg/L
1	2022	2065
2	2022	2065
3	2017	2029
4	2016	2027
5	2016	2024

11.1.2 Compliance with Regulations

All alternatives are eventually expected to result in compliance with applicable regulations. Alternatives 1 and 2 allow for continued migration of the plume. Because those alternatives involve no active remediation, chemical-specific regulations would be met only when contaminant concentrations decrease below cleanup standards by natural attenuation. Alternative 2 includes monitoring to confirm this occurs, Alternative 1 does not. Alternatives 3 and 4 include active treatment to ensure that applicable standards are met.

11.1.3 Long-Term Effectiveness and Permanence

The source area has been removed so residual soil contamination is unlikely to compromise the permanence of the remedial alternatives once completed. All of the alternatives would permanently achieve the cleanup goals; however, time to cleanup would vary. Moreover, Alternatives 3, 4 and 5, which include active treatment of the plume, may result in fewer uncertainties over the long term regarding the fate and transport of the plume.

11.1.4 Reduction of Toxicity, Mobility, or Volume through Treatment

Alternatives 3, 4 and 5 reduce the toxicity, mobility and volume of contaminated groundwater through treatment. Alternatives 3, 4 and 5 would extract 13.9, 13.2 and 11.6 pounds of perchlorate respectively.

11.1.5 Short-Term Effectiveness

Alternative 5 would cause the greatest impact to the environment, community and workers and includes the installation of two extraction wells. Alternatives 2, and 3 and 4 have the least impact on workers, the community, and the environment since they require only limited construction activities. In addition, all alternatives would eventually involve construction to decommission the wells and treatment facilities. Alternative 1 would have the least impact on the community or workers because construction is minimal.

11.1.6 Implementability

None of the alternatives is limited by administrative feasibility. Alternative 1 is the most easily implemented alternative since it requires no further action other than abandoning system infrastructure, groundwater monitoring wells and preparing close out documentation. Alternatives 2, 3 and 4 are the next most easily implemented alternatives with groundwater monitoring, O&M of the existing ETI system (for Alternative 3) and Land Use Controls. Alternative 5 would require installation of two new extraction wells. The Massachusetts Army National Guard's Revised Limited Authorization for Lead Ammunition Training (AO2,

Appendix C) at Tango, Juliet, and Kilo Ranges is conditioned on such coordination and specifically provides that investigation and cleanup take priority in the event of a conflict.

11.1.7 Cost

The costs of the alternatives increase as the amount of treatment increases.

Alternative 1 – present value cost of $0.21 million
Alternative 2 – present value cost of $2.8 million
Alternative 3 – present value cost of $5.8 million
Alternative 4 – present value cost of $5.3 million
Alternative 5 – present value cost of $10.7 million

11.1.8 State Acceptance

This criterion will be addressed in detail following comments received on the Remedy Selection Plan.

11.1.9 Community Acceptance

This criterion will be addressed in detail following comments on the Remedy Selection Plan.

11.2 Eastern Area

For reference, a brief description of each alternative follows:

Alternative 1 – No Further Action. Monitoring wells would be abandoned and site-closeout documentation would be completed.

Alternative 2 – Monitored Natural Attenuation with Land Use Controls. Alternative 2 includes long-term groundwater monitoring until COC concentrations attain cleanup levels and Land Use Controls.

Alternative 3 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls. Alternative 3 includes the continued operation of the current J-2 Range eastern groundwater plume ETI system. The J-2 Range eastern groundwater plume ETI system consists of three axial extraction wells pumping at a combined rate of 425 gpm and three infiltration trenches located to the northeast, southeast, and southwest of the eastern J-2 plume.

Alternative 4 – Focused Extraction with Three Wells, Monitored Natural Attenuation and Land Use Controls. Alternative 4 includes the continued operation of the current J-2 Range eastern groundwater plume ETI system with optimized pumping rates. The existing ETI system wells would operate at a total combined pumping rate of 495 gpm.

Alternative 5 – Focused Extraction with Five Wells, Monitored Natural Attenuation and Land Use Controls. Alternative 5 includes the continued operation of the current J-2 Range eastern groundwater plume ETI system with optimization of the pumping rates and the installation of two new extraction wells (one shallow and one deep) for a total combined pumping rate of 850 gpm.

The strengths and weaknesses of each alternative are presented in a narrative that addresses each criterion.

11.2.1 Overall Protection of Human Health and the Environment

Alternatives 2 through 5 would be protective of human health and the environment. Alternative 1, however, offers no monitoring or confirmation of existing Land Use Controls to ensure that future exposures do not occur. Alternative 2 adds provisions for plume monitoring and Land Use Controls to help prevent future exposure to contaminated groundwater. Alternatives 3, 4 and 5 add extraction and treatment components and achieve risk-based concentrations earlier.

Alternative	Estimated Year for RDX Cleanup Times (year)			Perchlorate Cleanup Times	
	6 µg/L	2 µg/L	0.6 µg/L	15 µg/L	2 µg/L
1	2014	2028	2055	2026	2104
2	2014	2028	2055	2026	2104
3	2014	2018	2023	2018	2027
4	2014	2017	2022	2018	2027
5	2014	2016	2021	2016	2022

11.2.2 Compliance with Regulations

All alternatives are eventually expected to result in compliance with applicable regulations. Alternatives 1 and 2 allow for continued migration of the plume. Because those alternatives involve no active remediation, chemical-specific regulations would be met only when contaminant concentrations decrease below cleanup standards by natural attenuation. Alternative 2 includes monitoring to confirm this occurs; Alternative 1 does not. Alternatives 3, 4 and 5 include active treatment to ensure that applicable standards are met.

11.2.3 Long-Term Effectiveness and Permanence

The source area has been removed so residual soil contamination is unlikely to compromise the permanence of the remedial alternatives once completed. All of the alternatives would permanently achieve the cleanup goals; however, time to cleanup would vary. Moreover, Alternatives 3, 4 and 5, which include active treatment of the plume, may result in fewer uncertainties over the long term regarding the fate and transport of the plume.

11.2.4 Reduction of Toxicity, Mobility, or Volume through Treatment

Alternatives 3, 4 and 5 reduce the toxicity, mobility and volume of contaminated groundwater through treatment. Alternatives 3, 4 and 5 would extract 13, 13.5 and 11.6 pounds of perchlorate and 2.9, 2.8 and 3.1 pounds of RDX respectively through the use of extraction wells.

11.2.5 Short-Term Effectiveness

Alternative 5 would cause the greatest impact to the environment, community and workers and includes the installation of two extraction wells, an MTU and infiltration trenches. Alternatives 2, and 3 and 4 have the least impact on workers, the community, and the environment since they require only limited construction activities. Alternatives 2, 3, 4 and 5 would require the construction of new monitoring wells. In addition, all alternatives would eventually involve construction to decommission the wells and treatment facilities. Alternative 1 would have the least impact on the community or workers because construction is minimal.

11.2.6 Implementability

Alternative 1 is the most easily implemented alternative since it requires no further action other than abandoning system infrastructure, groundwater monitoring wells and preparing close out documentation. Alternatives 2, 3 and 4 are the next most easily implemented alternatives with groundwater monitoring, O&M of the existing ETI system (for Alternatives 3 and 4) and Land Use Controls. Alternative 5 would require installation of two new extraction wells.

11.2.7 Cost

The costs of the alternatives increase as the amount of treatment increases.

Alternative 1 – present value cost of $0.24 million
Alternative 2 – present value cost of $3.2 million
Alternative 3 – present value cost of $5.5 million
Alternative 4 – present value cost of $6.0 million
Alternative 5 – present value cost of $9.5 million

11.2.8 State Acceptance

This criterion will be addressed in detail following comments received on the Remedy Selection Plan.

11.2.9 Community Acceptance

This criterion will be addressed in detail following comments on the Remedy Selection Plan.

Notes:
bgl = below ground level
BH = borehole
Crdmeth - coordinate method
Elev. = elevation
ESTIM = estimated coordinates
ft = feet
GPS = Global Position System
msl = mean sea level
N83UTM m = North American Datum 83 Universal Transverse Mercator coordinates in meters
NA = not applicable
SRVEY = surveyed coordinates
TOC = top of casing
WL = monitoring well

Notes:
NA = not analyzed
ND = nondetect
HA = health advisory
HMX = octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine
MMCL = Massachusetts maximum contaminant level
RDX = hexahydro-1,3,5-trinitro-1,3,5-triazine
µg/L = micrograms per liter
bgs = below ground surface

		Area 1	Area 2	Area 3	Area 4						
Significant Pre-Investigation Findings											
Brick-Lined Pits 1 and 2	3-14, 3-18		X	X		X	X	X		yes	disposal pit containing predominantly inert rounds.
Munition Survey Program Phase III Polygon Investigations											
J2P-1	3-18			X		X	X	X	12	yes	3 sub-polygons consisting of multiple munitions burial (1) and burn (2) pits
J2P-2	3-18			X		X	X	X	59	yes	24 sub-polygons consisting of multiple munitions burial (2) and burn (14) pits
J2P-3	3-18			X		X	X	X		no	4 sub-polygons investigated
J2P-4	3-18			X		X	X	X		yes	One munitions burial pit
J2P-5	3-18			X		X	X			no	
J2P-6	3-14		X			X	X	X		yes	4 sub-polygons consisting of (3) burial pits. Investigated in conjunction with Polygon 7
J2P-7	3-14		X			X				yes	Impact area. Investigated in conjunction with Polygon 6
J2P-8	3-14		X			X	X			yes	One munitions burial pit
J2P-9	3-14		X			X				yes	Impact area
J2P-10	3-14		X			X	X	X		yes	One munitions burial pit. Investigated in conjunction with Polygon 11
J2P-11	3-14		X			X				no	Impact area. Investigated in conjunction with Polygon 10
J2P-12	3-14		X				X			yes	
J2P-13	3-14		X			X				yes	One munitions burial pit.
J2P-14	3-14		X			X	X	X		yes	3 sub-polygons consisting of one burial pit. Investigated in conjuction with Polygon 15
J2P-15	3-14		X			X	X	X		yes	3 sub-polygons consisting of one munitions burial pit. Investigated in conjuction with Polygon 14
J2P-16	3-14		X			X	X	X		yes	One munitions burial pit.
J2P-17	3-14		X			X	X			yes	One munitions burial pit. Investigated in conjunction with Polygon 18.
J2P-18	3-14		X				X			yes	Investigated in conjunction with Polygon 17.
J2P-19	3-14		X				X			yes	Investigated in conjunction with Polygons 20 and 21.
J2P-20	3-14		X				X			yes	Investigated in conjunction with Polygons 19 and 21.
J2P-21	3-14		X				X			yes	Investigated in conjunction with Polygons 19 and 20.
J2P-22	3-14		X				X			no	
J2P-23	3-14		X				X			yes	Investigated in conjunction with Polygons 24 and 25.
J2P-24	3-14		X				X			yes	Investigated in conjunction with Polygons 23 and 25.
J2P-25	3-14		X				X			yes	Investigated in conjunction with Polygons 23 and 24.
J2P-26	3-12	X					X			no	Investigated in conjunction with Polygons 27, 28, 29, 30, and 31.
J2P-27	3-12	X					X			no	Investigated in conjunction with Polygons 26, 28, 29, 30, and 31.
J2P-28	3-12	X					X			no	Investigated in conjunction with Polygons 26, 27, 29, 30, and 31.

BIP = Blow-in-Place
MD = Munitiond Debris
RRD = Range Related Debris
cy - cubic yard(s)

NOTES:

Sort Type
SC - Composite Sample
SD - Discrete Sample
BIP - Blow in Place
BLP - Burial Pit
BNP - Burn Pit
SB- Soil Boring
EXP - Explosives
Herb - Herbicides
PCBs - Polychlorinated Biphenyls
ft = feet
bgs = below ground surface

Analytical Method
Pest - Pesticides
VOC - Volatile Organic Compounds
SVOCs - Semi-Volatile Organic Compounds
TOC - Total Organic Carbon
RAD-U- Radionuclides-Uranium
Perc- Perchlorate

Plan
JLWP- Final J-1, J-3 and L Ranges Work Plan
ADWP1- Additional Delineation Work Plan No. 1
ADWP2- Additional Delineation Work Plan No. 2
RR - Rapid Response
MSP - Munitions Survey Program
SSWP- Supplemental Soil Workplan
CIA- Central Impact Area

NOTES:
SC - Composite Sample
SD - Discrete Sample
BIP - Blow in Place
BLP - Burial Pit
BNP - Burn Pit
SB- Soil Boring
EXP - Explosives
Herb - Herbicides
PCBs - Polychlorinated Biphenyls
ft = feet
bgs = below ground surface

Pest - Pesticides
VOC - Volatile Organic Compounds
SVOCs - Semi-Volatile Organic Compounds
TOC - Total Organic Carbon
RAD-U - Radionuclides-Uranium
Perc - Perchlorate

JLWP - Final J-1, J-3 and L Ranges Work Plan
ADWP1 - Additional Delineation Work Plan No. 1
ADWP2 - Additional Delineation Work Plan No. 2
RR - Rapid Response
MSP - Munitions Survey Program
SSWP - Supplemental Soil Workplan
CIA - Central Impact Area
